## Sixutific Ammerican.

NEW YORK, MARCH 31, 1855.

## Ice Ehips

When the surface of the earth is uncover ed on Manhattan Igland, but especially on Long Island, we behold innumerable loose rocks, of every size, from the small cobble of a few pounds to the large block of many tuns weight. Some of these are much water worn, while others are rough and jagged.They are also of great variety with regard to their composition. Some are of white granite, like that of the Sing Sing quarries others like the dark grey granite of Staten Island ; and others, again, are of the schist ose class. These rocks grew not where they are found, and no human hands carried them thither. Whence came they, and how have they been deposited, far and wide, over such an extent of country, like buge bail stones dropped by successive showers? The only plausable theory for their presence is, that those places where they are now found, were once the bed of the sea, over which icebergs floated from an arctic ocean, with thesestone attached to their sides and base, and were dissolved by warm currents of water, and theas relieved of their stony cargoes. In the northern seas, the ice forms to a great deptb and grasps with its strong cold hand large and small rocks, at the sea bottom and on the shore. When spring comes, these are lifted up by the powerful thaw and water swell and are floated off into the ocean, with their cargoes of rough stones wrenched from the rocky shore, and water worn boulder lifted from the sea bottom and beach. Carried out on the cold ocean currents setting from the north to the south, these iceberg at last disappear, by dissolution in the warm currents of the tropics, and, as a consequence their rocky freights are strewn over the bot tom of the sea. In the epring of 1838, a block of granite, estimated to weigh $1,000,000$ pounds, is stated by Prof. Von Baer, of St. Petersburgh, to have been carried by ice from Finland to the Island of Hoagland and it is well known that buge blocks of granite are carried down by the ice every season from Finland, and deposited along the bottom of Copenhagen Bay. This is the manner, no doubt, by which all Long Island and much of the eastern coast of our cont nent came to be covered with boulders.
What powerful influtnces must bave bee at work, by which parts of our country now dry land, were once covered with the beating surges of ocean; then the wild waves repelled again, and the bills and valleys arising out of and above them. To conceive of a period in the bistory of our country when tall icebergs floated over the place where the city of New York now stands, seems to be a draft upon the imagination as heavy, as to believe in Aladdin's "Wonderful Lamp." But, if this "iceberg boulder theory" is correct, we must believe it ; there is no other belp for us.

## Phyolcal Geography of the Gea.

A new science, which has received the above name from Baron Humboldt, has come into existence within a very few years, and the credit of its authorship belongs to a Lieutenant of the Americannary-M. F. Maury, L. L. D. The first distinct work on the subject, for public sale, has just been issued by Harper \& Brothers, and we find that it is dedicated in a gentle spirit by Lieut. Maury to George Manning, of this city, who bas done so much to disseminate information on the subject. The physical grography of the sea relates to its winds, currente, temperature, character of its waters, its dep ths and shoals. By charts, it presents the different tracks of vessels on the ocean, and then exbibits the winds and currents which they meet at different seasons of the year. These charts are made from the logs of numerous navigators, and have proved of immense benefit to the nautical world. Before the comefit to the nautical world. Before the com-
mencement of publishing these charts. the average parsage from New Yort to Califor nia was 183 days; it is now reduced to 135
days. Between England and Australia, the average time of going, without these charts, was 124 days, and the coming about the same time. The outward passage is now reduced to 75 days. The saving to the United States
trade with California and Australia, by shorttrade with California and Australia, by short-
ening the voyages, amounts to more than ening the voyages, amounts to more than
$\$ 2,250,000$ per annum. Nearly all the nations of the world are now unitedly engaged in advancing and perfecting this science. A conference was held in Brussels in Aug. ust, 1853, at the suggestion of the United States, consisting of representatives from France, England, Belgium, Russia, Sweden, Holland, Denmark, Portugal, and the United States, which recommended a plan of obser vations to be followed on board of vessels of all friendly nations. In peace and in war hese observations are to be carried on, aud n case any of the vessels on board of which they areconducted may be captured, the logs of them are to be beld sacred. "This," says Lieut. Maury, \% is a sublime spectacle presented to the scientific world: all nations greeing to unite and co-operate in carrying ut one system of philosophic research, with regard to the sea. Though they may be enemies in all else, here they are friends. Every ship that navigates the high seas, with charts and blank abstract logs for observations, may benceforth be regarded as a floating
 must thrill the beart of every lover of science. It is greatly to be regretted that all these nations are not as friendly in the puruit of national and commercial objects, as they are in the "science of the sea."
Although a great deal has been done in a few years, principally by American sailors, in collecting information for the preparation of the "wind and current charts;" much yet remains to be accomplished. A vast amount of the great ocean spaces between Europe and the East Indies is almost unknown. In an outward voyage to India, the Atlantic ba:* generally been crossed three times by navigators instead of only once, owing to one captain following in the route of another, so as to get such winds as were stated to prevail, for wafting their ships to the desired havens. Great activities are now at work to discover new and favorable routes, and thus make shorter voyages ; these we bave no doubt will be crowned with complete success.

## Fencing Rallways.

The State of Illinois is the frst which bas adopted measures to fence in all railroads, in order to prevent cattle straying on the track. This we recommended years ago. We bope every State in our Union will soon follow in the footsteps of Illinois. The law passed by the Legislatnre of that State provides that every railway now in operation, or which shall be bereafter placed in operation, shall erect and mainain good and sufficient fences on the sides of their roads, with openings and gates at the farm crossings, fufficient to prevent cattle from getting on the road.And when such fences and guards are not erected and in good repair, the Company shatl be liable for damages done by them to cattle which may get on the track, but if the fences and guards are erected and in good repair, th +y shall not be beld liable unless the damage was wilfully done. Said fences need not be built through unoccupied lands lying at a greater distance than five miles
from ang settlement. Ang person who shall from ang settlement. Ang person who shall road, except at the crussings, or tear down the fences or guard thereof, shall be liable to a fine of not more than $\$ 100$, and for all damages sustained thereby.

## Medicinal Effects of Ealeratus.

A writer in the Medical Examiner, criticises the paper of Dr. Alcott, originally pubhished in the Boston Medical and Surgical Journal, on the injurious effects of saleratus as used in domestic cookery, and especially in attributing the great mortality among children under five gears of age in our country, to such use of it. No less than threefirths of the deaths of children were attributed to its use, without any attempt to substantiate suoh a bold assertion by facts, ex
cepting the placing of it among irritant po:s ons, because Orfila bad done so. Common salt is also set down by Orfila as an irritant poison when excessively used. The critic in the Examiner tells Dr. Alcott that he forgot to mention that one-balf of the children that die under five years of age never tasted bread nor saleratus. He asserts that "if the ill consequences resulting from careless cooking were properly estimated, it would be found that much disease might be traced to sour and badly fermented bread." Saleratus, he asserts, will produce no injurious effects from constant use in such small quantities as are required for making bread. How true these views make the old saying, "doctors do differ."

Patent Tea and Cofree Pot.

The annexed engraving is a side elevation partly in section, representing an improvement in the construction of coffee pots, for which a patent was granted to James MacGregor, Jr., No. 117, Beekman street, this city, on the 11 th of April last year.
The nature of the improvements, consists, irst, in surrounding the bottom (or bottom and sides as far as may be desired,) of the tea or coffee pot, with an outer case, which may or may not be attached to the tea or coffee pot, leaving a space for water between the two cases, below the bottom of the tca pot, while the tea or coffee is being prepared,here is no loss from evaporation, and the cotfee or tea may be steeped somewhat longer to advantage than in the common mode.
Second, in baving a mouth-piece to the outer case, for the purpose of pouring water between the two cases, and for the escape of steam made between the two cases; while the pot is on the beating apparatus this mouthpiece is always to be kept open. When it is removed from the beating apparatus, this mouth-piece may be covered to retain beat. The space between the cases should not be filled more than three-fourths full, thereby allowing free escape to the steam made between the two cases, and by that means preventing the water in the pot from rising much above boiling beat. The inner case or pot, where the tea or coffee is put, is generally made as much smaller below where the outer case is to join as is desired for water space. Thus leaving the outside of a uniform appearance. The handle is put on the side half' way between the spout and mouthpiece, they being exactly opposite to each other.
Third, in having an air-tight cover to the spout and top of the pot, of sufficient weight and adbesion to cause pressure sufficient to prevent the tea or coffee from boiling while being drawn or prepared. The pot and all parts are generally made of tin.
$A$ is a small ball valve in the spout; $B$ is the cover of the pot; $C$ is the space for tea or coffee. D is the space for water between the two cases. $e$ is the mouth-piece attached to the outer case, for the admission of water, and the exit of steam by a channel, $E$.
Directions for Usina-Put the necessary amount of tea or coffee into the pot to make the desired quantity; then fill the pot with boiling water, sufficient to give the required amount, and carefully put the cover on ; fill the space between the two cases (by pouring in at the mouth-piece at the bandle, twothirds full. The cover to this mouth-piece is
ing apparatus, or stove, to let the steam off, and to be closed when it is taken off, to retain the heat. The water between the two cases, while the pot is on the heating apparatur, should boil, but not vehemently. Tea will seldom require to have the water in the outer case boil more than ten minutes, and coffee fifteen to twenty minutes; then the pot can be taken off the beating apparatus; the cover on the mouth-piece should be closed and the pot left (if time is not pressing,) for tea about ten minutes, and for coffeeabout twenty minutes-more time does no harm. It maystand for hours without injury. The coffee roasted in the usual mode is ready for use without grinding, thereby preventing all sediment from the coffee. If the above time is taken, no loss is sustained by not grinding. By the use of one of these pots, a much superior tea and coffee liquid is obtained than by common pots, and with less tea and coffee. This we bave proved to our satisfaction; the improvement is a most excellent and economical one, and will effect a considerable saving in every family in which it is used.
These pots are manufactured and cold by Mr. MacGregor, at the above named place.

## Railroad Bienals.

The Railroad Advocate, in the above question, is like an eel that has tied itself into a knot so tight that it cannot get loose. It made a voluntary wrong statement, and it wriggles and wiggles in itsown mud to bide it ; but all won't do. In the last number, it flies for consolation to that reviler of every-thing.American-the London Mechanic's Magazine. It is welcome to such company ; as distinguished for its profound ignorance as it is for its vapid conceit.
The Railroad Advocate characterizes the Mechanic's Magazine as " one of the ablest and most respectable journals of the kind in the world," thus evincing its practical ig. norance of that publication. This is only a chip under which it attempts to bide its own slender proportions; a mereattempt to throw dust into its readers' eyes.
To show the power and force of its English authority, it is only necessary to state, that after more than a generation of years (according to a statement recently published in the Tribune,) its stamped issue amounts to about three hundred copies. "Full many a flower is born to blush unseen."
The fact is, the Mechanic's Magazine, like the Railroad Advocate, is able and respectable only for its insignificance to do good or evil; allelseis purely imaginary ; and the affiliation between the two is appropriate and consoling.

## Engravers Advancing.

Samuel Cousins, the distinguished London engraver, has been elected a full Royal Academician. He is the first engraver who has been admitted to such an honor. Bartolozi was elected, not as an engraver, but as a designer. There is a talk of admitting another engraver a full Royal Academician, making the number of academicians fortytwo instead of forty; but certain schoolboy conditions will, it is said, have to be complied with, which the most eminent engravers are unwilling to fulfill.

Amendment of the Patent Lnws.
An amendment was made by our late Congress, at the request of the Commissioner of Patents, providing for four new principal examiners, four assistant examiners, and the power to employ two other principal, and two assistant examiners, if required. This amendment to the patent law confirms regu lations beretofore adopted by the Commissioner.

## Coal Pit Explosion.

A severe explosion, by which 35 miners lost thei r lives, took place in the Midlothian Mine, near Richmond, Va., on Monday laet week. It was caused by breaking into an old shaft which was filled with fire damp. There were fifty in the pit at the time ; those not instantly killed it is supposed will not not instantly killed it is suppo
live, owing to severe injuries.
