Scientific American.

(For the Scientific American.) Photogranhy.

In a late number of the SCIENTIFIC AMERI-CAN you give the new discoveries of Mr. Mascher; the reason of my now addressing you | nished with positive proof to the contrary, is to remind your readers of facts long known we must entertain the opinion that he has ground glass. cannot imagine for a moment Porta, of Padua, every photographer knows, ed by Sir David Brewster. discovered the camera obscura, and Mr. Hunt, in his treatise on Photography, page 33 American edition, says; "Its principle will be best understood by the very simple experiment of darkening a room by closing the window shutters, and boring a small hole in them. If a piece of paper is held at a little distance from this hole, the figures of external objects will be seen delineated upon it, and by putting a small lens over the hole they are rendered much more evident, from the condensation of the rays by the spherical glass, If, instead of a darkened room, we substitute a darkened box, meaning a camera, the same effect will be seen to result." This I presume is sufficient to show that Mr. M. is not the discoverer of the camera obscura, for it is this precisely he claims.

Further on Mr. Mascher informs us it is self-evident we have the means of doing with one camera that for which two were deemed indispensable. I refer again to Mr. Hunt's treatise, page 308, English edition, he says: "Sir David Brewster contends that it is not practicable to obtain sufficient exactness by either of these methods, alluding to the use of two cameras with lenses of the same focal length, and with one camera and one lens, by adjusting it at a certain measured distance from the object to be copied, and having obtained one picture, move it round about 20 degrees and take the second image. Sir David Brewster therefore proposes the use of a binocular camera, which he thus describes : In order to obtain a photographic picture mathematically exact, we must construct a binocular camera which will take the pictures simultaneously, and of the same size, that is, a camera with two lenses of the same aperture and focal length, placed at the same distance as the two eyes. As it is impossible to grind and polish two lenses, whether single or achromatic, of exactly the same focal length, even if we had the very same glass for each, I propose to bisect the lenses, and construct the instrument with semi-lenses, which will give us pictures of precisely the same size and definition. These lenses should be placed with their diameters of bisection parallel to one another, and at a distance of two and a half inches, which is the average distance of the eyes in man, and when fixed in a box of sufficient size, will form a binocular camera, which will give us, at the same instant, with the same lights and shadows, and of the same size, such dissimilar pictures of statutes, buildings, landscapes, and living objects, as will re-produce them in relief in the stereoscope."

Mr. Mascher informs your readers that Sir David Brewster, and a host of others, as far as practical results are concerned, never determined the proper stereoscopic angles; the above proves a different story.

As regards the superiority of small lenses don in bags to gardeners and farmers like over large ones, every practical photogenist guano. knows it; yes, most amateurs, even, know Neither coal nor wood undergo perfect the superiority of small over large lenses, combustion, when smoke passes off-the and as Mr. Mascher justly observes, pictures smoke is a black loss. In a stove or furnace taken with large lenses produce distortions, which burns coal or wood perfectly, gas, but I believe, and the majority of artists will which passes off, is mostly carbonic acid, and bear with me, that the distortions are not to we can assure our correspondent that it is don Society of Arts, by Prof. Wilson, on the the extent represented, but they may, by a pretty sharp gas. careful examination, be discovered in the He is mistaken also about the difference of ed the prize for superiority in quality to the finest photogenic portraits to a greater or diffusiveness in coal and wood smoke. The Cause of Drought.

MESSRS. EDITORS-With your permission I will lay before you numerous and scientific readers what I imagine to be the cause of drought. I believe it is caused by the burning of coal; that the smoke arising therefrom is injurious to vegetation, to the soil, to the air, and to the clouds. The ashes portion of the steam, and he bases this hyfrom coal are of no use to the farmer, it de- pothesis on the assumption that steam conpreciates his soil, whether thrown upon it or tains twelve times its volume of hydrogen, falling upon it in particles from the smoke. which assumption is greatly at variance with Coal smoke has no sharpness in it, to irritate known facts. A cubic foot of oxygen weighs and stimulate plants; it is entirely devoid of 592 grains, instead of 48 grains, and the moisture, and it, in my opinion, counteracts the formation of clouds, especially "cirrus," The constitution of vapor of water, therethe scarcity of which, for some time past, has fore, is two volumes of hydrogen and one of been observed. The smoke from wood, on oxygen condensed into two volumes, so that the contrary, has all the properties which it contains only its own volume of hydrogen. coal has not. This subtle fluid, I think, pen- Consequently if steam were decomposed in etrates the atmosphere of the whole world a boiler by the hot iron absorbing its oxyon account of its diffuseness.

The sublimity and grandeur of the clouds, to my vision, are nearly destroyed, and the powers of the heavens "are considerably weaker, and may gradually grow less as coal coal speculator, I wish prosperity to the that if the jet p p be made perfectly clean, whole human race. If my belief can be substantiated by any of your scientific correspondents, the removal of such a cause will be of more importance to the world than war in Europe or the acquisition of Cuba to the United States. ONE OF YOUR READERS. Baltimore, April 28th, 1855.

[Our correspondent has not given us a single reason for his belief in coal smoke being the cause of drought. We take this occasion, however, to impart to him some scientific information.

He says that coal smoke has no sharpness in it-does not irritate and stimulate plants. is devoid of moisture, and therefore he concludes it counteracts the formation of clouds. Now suppose all this were true, no reason is afforded him for coming to such a conclusion. The same reasons might as well be presented for coal smoke being the cause of rains, during a wet season. During very dry and very wet seasons, a thousand-and-one reasons are generally given by as many different theorists, as the cause for such seasons; whereas the causes are beyond all our speculations. Wet and dry seasons have occurred since the flood, and theywill continue to occur to the end of time, irrespective of the use of any kind of fuel.

The smoke of bituminous coal and wood is the same in composition ; there is no difference, for the coal is of vegetable origin.

However useless coal ashes may be, we know that coal smoke (soot) is excellent for plants, and contains considerable potash. Our correspondent is mistaken respecting its qualities in agriculture. It is sold in Lon-

(For the Scientific American.) Chemistry of Steam Boller Explosions.

Permit me to rectify a few errors into which your correspondent, J. B. Conger, has fallen in his article on the Chemistry of Steam. He seems to think that the sudden explosions which semetimes happen in steam boilers may be caused by the decomposition of a same bulk of hydrogen weighs 37 grains. gen, the hydrogen set free would not exert a greater elastic force than did the steam. Philosophers are now generally agreed that the electricity excited by a jet of high pressure steam is to be ascribed to friction. and the electricity will be positive, while the introduction of the least particle of oily matalways be of the same kind. But however it may be excited, it cannot decompose water, for galvanism is the only kind of electricity which can directly produce chemical SIMON NEWCOMB. changes. Sudlersville, Md., April 28, 1855.

Inventions Wanted.

MESSRS. EDITORS-Permit me through the attention of inventors to some of the wants of the country physicians of the United besides heating every part theeof, and se-States. First, A small scale which would 'curing families from that universal destroyaccurately weigh from half a grain to twenty grains, is much wanted. It should be no larger than a pocket pen holder, and the with a delicate spring; it seems to me such a thing might be constructed, and if it could of buggy wheels be so made as to be greased from an oil can without taking off the wheels? In the course of nearly twenty years' practice, in a hot, dry climate, and several buggies, and find that frequent greasing is absolutely necessary. It ought to be done every day, and it is a troublesome operation as at present performed. I hope that these suggestions may meet the eye of some of our ingenious mechanics. AN ALABAMA PPYSICIAN.

April 20th, 1855.

We have never seen an invention to meet the first want of our correspondent, but if he examines page 60, Vol. 8, he will find one illustrated to meet his second.

very dry; by so doing it will leave the small Our correspondent need not have his fears cells open-lay it on the shelf where they are will slay them by the thousands, and soon rid the house of these troublesome insects. When you squeeze the sponge, you will be astonished at the number that had gone in the cells."

----Ruttan's System of Ventilation.

A new county jail lately erected at Oxford, Canada West, is warmed and ventilated under Ruttan's plan, and we learn that other institutions of the same character in Canada, are likewise to introduce it. The Oxford Grand Jury were so highly satisfied with the operation of Mr. Ruttan's system, that they introduced the subject in their stated presentment as follows:

"And the jury aforesaid, upon their oath, do further present that they have had their attention especially directed to the system of warming and ventilating the cells and rooms of which they are informed that Mr. H. Ruttan is the inventor, and to them it seems that this system is so nearly perfect as to meet the entire wants of the case, and to leave scarcely anything to be desired."

Mr. Ruttan's method has been often referred to in our columns. (See engravings also on page 299, Vol. 6, Sci. Am.) We have long is used among men. I am neither a wood nor not to mere evaporation. Faraday has found regarded it as the only truly economical and effective way of ventilating city and other buildings with which we are acquainted, while for large public institutions of every ter will cause it to become negative. If it character it is equally admirable. By its were produced by the evaporation it would use, the temperature of apartments, no matter how numerous they may be, can be steadily kept at any desired point in winter, at the same time that a ventilator imperceptible but most thorough, is in constant operation. In summer the ventilator is equally excellent. We wonder that the officers in charge of the erection of our school houses, prisons, churches, hospitals, &c , have never adopted this, or some kindred system. In medium of your valuable paper, to call the sll private dwellings its introduction effects a saving of fifty per cent. or more in fuel, er of health-impure air.

We regret to learn that the large and splendid passenger car on the Erie Railroad, pan need not be larger than a half dollar, which was fitted up for ventilation on Ruttan's plan, and which has been used with so much success for several months past, was be combined with a small minimeterso much | burned in the fire which consumed the railthe better. Second, Cannot the axle boxes | road depot of Jersey City, a few days since. We have been told by a gentleman who is a frequent traveler over the road, that when Ruttan's car was in the train it was always crowded; the passengers would leave over a dusty or sandy soil, I have used up the other cars, where there was plenty of room, to enjoy the pure atmosphere, even temperature, and freedom from dust, which this improvement effected. It is said that the car was just as warm at the seats nearest the door as in the center, and that the air on the floor was heated just as much as next the roof. The heating was done by one small stove.

Eclipse of the Moon.

The total eclipse of the moon on the night of the 1st inst. was a fine scene. We thought as we witnessed the dark shadow of the earth stealing over the moon's disk, of the many telescopes that were then pointed to it, and the light which science had thrown around the phenomenon. At one time-not many years since either-people in their ignorance believed that such events were precursors of evil, social and national, such as death, war, famine, or pestilence. The Hindoos believe that an eclipse of the moon is caused by a great serpent-a spirit of evilendeavoring to swallow the moon. Astronomy is now perhaps the most exact of sciences. The very moment when an eclipse will take place can be predicted years before-hand.
