## COAL AND A SUBSTITUTE.

In our last issue we referred to the sabject of the anticipated exhaustion of the coal beds of Grea Britain as having engaged the attention of Parliament, through the agency of sach eminently practical men as John Stuart M1ll and Mr. Gladstone. That there is some reason for the anxiety manifested by these gentlemen, at least so far as coal is con cerned, there can be no doabt, bat we do not sabacribe to the opinion that, with the last tun of coal, goes the weltare of the toiling millions of England. Coal, either bituminous or anthracite, is not a con densed form of carbon. It is balky, and in combastion leaves a large residuam of no value at all as a fuel. Already, even in this country, where the supply is apparently inexhaustible, invention is busy to provide a sutstitute for coal, or rather to procure a better and less balky article of fael. Of course the growth of our forests cannot be depended apon, us wood is more valuable for other parposes, and its balky nature, even it it could outlast a handred generations, would prevent it from ever superseding the fossil fuel now so generally used.
Bat there is another sabstance more generally diffused iu all countries than either wood or coal, and one which is being continually formed. This is peat, which in some respecta has qualities as a fuel tar in advance of coal. It is now being manufactured by disintegration and compression, and pat in use for stationary and locomotive engines. For many years it has been used in its crade state for domestic parposes in this country, and in Ireland it is the common fuel. The "bogs of Ireland" are immense re ceptacles or reservoirs of this sabstance-the debris ot dead vegetation-ayd in Wales and many portions of England it abounds. It is not less common in this country, and since coal has ruled so bigh, attention nas been tarned to this sabstantial in plentitul and 80 easily obtained. It is said to give, weight for woight, a much greater heat than coal, and for foundery and smelting parposes, is superior, as being entirely free from sulphar.
The bogs, or meadows containing peat, are in many locallties continually encroaching apon the firmer land. The movement of the immense masses of decayed regetation in morasses between hills or on the slopes of morntain ranges, is analagous to that of the glacier-imporceptible bat sure and certain. There are cases in England, in Scotland; and even in thle country, where the boge have pusbed thelr boundarlea, year by jear, antll large tractis of valuable
farm lands have been overwhelmed and rained. Here, then, are inexhanstible mines equal to those of coal, and having the advantage of being on the surface and easily wrought.
Bat the experiments in working petroleam as a fuel have not yet proved failures. There is bat little doabt but this sabstance will be made to occapy an important position in the economy of domestic and manafacturing enterprise, so soon as its prodaction in quantity sufficient will reduce its cost to a figare which will anthorize its employment as a fuel.
Common pitch, from which the spirit of turpentine is distilled, has been triedin a pnlverized state by a Russian naturalist, and is now being tested by the Rassian Admiralty as a fuel for generating steam in the boilers of steam frigates. The resalt thas far has been, report says, eminently satisfactory.
A French chemist claims to have realized the fable of bottling up sunlight by means of acetate of soda. Ha claims that by evaporation, after being conlined, this sabstance will give oat a strong heat. If he is successfal our Engllish friends of this generation may be able to carry in their pockets portable atoves for warming the outer man as many now carry stomach warmers.
Seriously, however, we cannot suppose that a dimination of the fuel now ased can occar to sach an extent as to threaten the prosperity of a great manufactaring nation without bringing with it a discovery which shall at least make good the loss.

## BREEGH-LOADING RIFLES FOR BPORTBMENT.

By reference to our Washington correspondence it will be seen that at least one man is ready to bet that, with his breech-loading rifle, he can surpass in accaracy any mazzle-loader that can be prodacedproving pretty conclasively that in the one thing needtul-accuracy-breech-loading rifies have at last reached a point of excellence equal to that of mazzle loaders. As they are greatly saperior to mazzle loading gans in convenience, ease, and rapidity of loading, and as they obviate the necessity of carrying into the woods a variety of apparatus-ramrod powder horn, charger, percassion caps, and in the case of false-mazzle guns, mallet and driver-they will now, no doubt, be generally adopted for sportiog purposes.
A very general defect in breech-loading rifles, made ap to the present time, has been a want of sufflcient weight in the barrel. For army parpores it is manitestly extremely desirable to have the arms of infantry soldiers made just as light as possible, the man being required to carry on foot a load of other thinga; but for any considerable range this lightness can be obtained only at the expense of accaracy. There is no use in offering to sportsmen a gan, however ex cellent in all other qualities, that is not absolutely perfect in accuracy. If there is anything which he regards with intolerable abhorrence it is a rifle that will not carry the ballet where it is pointed.
A very light rifie is pecaliarly objectionable for those long ranges which are now in universal vogae. For those ranges it is necessary to have heavy elongated ballets and large charges of powder, producing a recoil which throws a light rifle oat of position, and atterly destroys all accuracy ol fire. The extent of the range is also diminished by lightness of the barrel. It was formerly sapposed that one-half of the force of the charge was expended on the shot and the 'her half apon the gan, bnt Professor Treadwell has demonstrated that the portion of the force expended on each is in pioportion to the distance which each is movel while the force is acting apon it-that is, during the passage of the shot along the barrel. This proposition was overlooked by a writer so well intormed as Professor Silliman, and so recently as 1858. Ic his "First Principles of Philosophy," page 22, he says, "By the principle that action and reaction are equal (27), we know that when a masket is dischargel the force of the explosion reacts apon the masket with the same intensity as it projects the ball. According to the princliples of momentam, the weight of the gon, malliplied by the velocity of the recoil, must be equal to the weight of the ball, malttplied by the velocity of ite projection, yet the recoll of the gan is received by the sportaman with perfect impanity, while the moving ball deals death or de atraction to opposing objects,"
Protentor Treadwell's oromoallion renulta from the
first principles ot mechanics. Work is measured by the amount of the force and the distance throagh which it acts, regardless of time. It is somewhat surprising, therefore, that the proposition has been so generally overlooked.
The fatal want of accaracy, and the diminished range of very light gans, may be well worthy of consideration by oar ordnanceofflcers in determining the weight of our army rifies.

## EDUCATING OTRER NATIONS.

Quite enough has been done, we think, in the improvement of other nations by our example alone, in originating, experimenting, and carrying to completion radical and valuable improvements in every department of mechanics, withoat carrying our achools to their doors and farnish:ng them with instractors grataitously. Of course it cannot be expected that any national improvement, the operation ot which mast be open to the inspection of foreign ers as well as our own people, can be kept a secret, bat it is not necessary for the government to spend handreds of thoasands for the parpose of combating foreign prejudice and compelling a recognition of our saperiority, when, if saccesstal, the resalt will be merely to enable other nations to equal us, and thus relatively redace our position.
The proposition of sending the Miantonomoh to Earope, In charge of Assistant Secretary Fox, osten sibly on a visit of ceremony to the Czar Alezander, bat really to exhibit our progress in naval affairs to Earopa, we do not really approve. It is unnecessary for us to go cruising aboat the world with a travel ing show, in order to gain the respect of other nations. The game is not worth the powder. We know that we are the peer of any nation that boasts a navs, and if we desire to prove it we have only to refer to the achievements of our monitors during the past four year?.
The resolutions of respect, sympathy, and congratulation, of which Mr. Fox will be the bearer, could as well be forwarded through our Minister at St. Peterabarg, as sent in one of our largest monitors at an expense of at least one handred thousand dollars.

Changes in Forms of Letters Patent.
We understand that Commissioner Theaker proposes some changes in the forms of patents issued to inventors. It is intended to reduce the size of the instrament from fifteen by twenty inches to ten by fifteen inches, thas rendering it of a more convenient size tor mailing. The present large vignette of the Patent Oflle will bereplaced by a mach smaller view of the Patent Offce, sarrounded by small medallion engravings. representing the advancement made in machinery in the present ceatary-all to be engraved in the highest style of the art, and printed on parchment paper. The seal of the Patent Offce, instead of the words, "Seal of the Patent Offce," will bereaiter centain "United States Patent Office," and the sentence below it, "Coantersigned and sealed with the seal of the Patent Office," will be omitted.
The specifcation for the patentee and the boand record in the Office will be printed instead of written as now. Another important improvement is in the manner of inserting the drawing, which is required to be ten by fifteen inches in dimensions. In the present form of patent the drawing cannot be newly nserted, bat in the form proposed it can be adjusted with newness and precision. These changes can be made, the Commissioner thinks, withont additional expense to the Government, and will render the patent a credit to the Office and to this Government, when sent abroad.

Steam omnibuses are to be established in Paris to ran from the Champ de Mars, the spot where the great exhibition is to be held, to the Place Bastilemating six halts. The distance is now traversed by horse omnibnses in one hoar and twenty minates. The ateam company undertake to accomplish it in forty-five minates including stoppagee.
The Evening Post of the 25th alt., intorme ns that a Weatern gentleman has discovered the lost art of hardening copper. Will some one kiadly inform ns who lost it, how valuable it was, and If the finder got gny rewsed ?
