fered severely from the intense heat, but the effect upon the pound." tubes, c., of the engine do not seem to have been yet noted.

These experiments do not give much encouragement that as follows: liquid fuel will ever be adopted except in special cases. The price of such fuel could not be kept at its present figure were phenomenon of life; it begins and ends with it; an alcoholic it in general demand for this purpose, and therefore its use fermentation without simultaneous organization, growth, and would not probably result in any economy over that of the development, that is, without continuous life, is impossible." best coal.

THE ECONOMY OF STEAM ENGINES.

Many persons, using steam engines, fail to appreciate the value of inventions designed to produce economy of fuel. It is true that sanguine inventors and unscrupulous agents of stock companies often promise savings that cannot be realized in practice, but no one should condemn, wholesale, all devices of this character, because from lack of judgment he has been once deceived. Neither should he reject offered assistance because the promised savings are ridiculously large. All matters of this character should be decided on their merits. Some may be valuable though overrated.

The coal bills of a steam engine foot up rapidly, and a very small percentage of saving will pay for a great many improvements. It is easy to show that it is true economy to sell an old steam engine for scrap iron and purchase an improved engine at full market rates rather than pay for the extra coal required by the former. For instance, there are tew engines working of the old style, regulating by the throttle valve, that furnish an indicated horse power for four and one half pounds of coal per hour. This is equivalent to say five pounds per hour for each net or effective horse power. An engine developing eighty net horse power would then require $(80 \times 5 \times 10)$ 4,000 pounds of coal per day, or say 4,200 including banked fires at night. This for a year, or 300 working days, would equal (4,200 \times 300 \div 2,000 \Longrightarrow) 630 tuns per year, which would cost, in many localities, upwards of four thousand dollars. Now, a new engine, with cut off adjusted automatically by the governor, of a size capable of furnishing economically eighty net horse power, costs from \$4,000 to \$4,500. So it is safe to say that engines constructed with no regard for economy, require yearly, for fuel alone, an expenditure of money equal to the first cost of a new engine. This would be true, also, in many places where fuel is cheap, if the original cost of the new engine were reduced by the sale of the old one, even for scrap iron.

From the above, then, it is evident that if the new engine gaves only ten per cent of the fuel, this saving is continually paying ten per cent interest on the cost of the engine, while the work is being done the same as before. This is as good as most investments; but when it is considered that any engine, with modern improvements, will save thirty and even forty per cent of the fuel, as compared with the results above mentioned, the rate of interest becomes correspondingly large, and the engine is paid for by the saving in fuel in three years or less, or in four to five years when fuelis much cheaper.

Similar considerations apply with equal force to steam boilers, and to many of the details of construction of both engines and boilers. Any device that saves fuel saves money; and if it do not introduce complicated parts liable to derangement, it should be encouraged.

The simple feed-water heater is a good example of this, and saves on the average ten per cent of the fucl.

LIEBIG ON FERMENTATION.

the part of many chemists during the last ten years, and has come out with one of those exhaustive and convincing replies that recall the best days of his great intellect.

The reticence he has observed has emboldened some of the younger chemists to disclose weak points in their attacks, cannot fail to attract the attention of scientific men every-¹ means that it is one of which the subject and predicate can while others have looked upon the dead lion as a harmless creature, and have incautiously come too near his claws. On the other hand the views of Pasteur on fermentation are

"The chemical process of fermentation is essentially a

He regards fermentation as a chemical process accompanied limits the splitting up of the atoms of sugar. Liebig says , that there is nothing new in this view of the process. It was include. fully understood and explained by him in his chemical letters twenty years ago, and then, as now, he did not care to adopt it.

The action of ferments on fermentable bodies, says Liebig, is analogous to that of heat on organic substances. Their decomposition at high temperature is always the result of a verted by heat into carbonic acid and acetone, just as sugar is split up by yeast into carbonic acid and alcohol; the carbonic Before reasoning from an asserted phenomenon, it demands acid resulting from the decomposition of the acetic acid con- to know the existence of the phenomenon. tains two thirds of the oxygen, and the acetone all of the hydrogen, in the same way as the carbonic acid of the fermentation of sugar includes two thirds of the oxygen, while the alcohol contains all of the hydrogen.

develops the living organism; but in the process of fermen- o'clock; this conflicts with his direct perception of relations. tation there is an action independent of, and outside of, any Such a proposition is inconceivable, and therefore would be products that the living organism can assimilate. The vital operation and the chemical action are evidently two phenomena, that in their interpretation ought to be considered separately.

To the opinion of Pasteur that the decomposition of sugar in the process of fermentation rests upon the formation and growth of the cells of the yeast plant, is opposed the fact that yeast will produce fermentation in a pure solution of sugar; gen and sulphur, also containing considerable quantity of salts of phosphates, it is difficult to comprehend how, in the absence of both of these constituents in the sugar, the growth of the plant cells can be promoted : and it would be equally difficult to explain how the beer yeast exerts the same decomposing action upon numerous other bodies as upon sugar.

Liebig has carried on an extensive series of researches in order to determine the action of yeast upon a great variety of principles, while the explanation of Pasteur is wanting in fashionable, to refer every vital action back to the formation of cells, and the building up of protoplasm, and to intimately connect life and matter together so as to gradually support the doctrine of spontaneous generation, that the publication test against the tendencies of the age. And it may serve as an intimation to younger men of science, anxious for fame, that the old methods of research are sufficient to furnish us with satisfactory explanations of the phenomena of nature without the necessity of having recourse to the supernatural school.

POSITIVE PHILOSOPHY.

The able exposition of the positive philosophy made by

It is thus seen that with the heavy oil, steam can be got up quires time; and the same is true of putrefaction itself. And relations and the attempted study of the essential nature of things.

> It says you may find out the how of existence by experi ence and observation, but from the nature of the case it is impossible for the human mind to determine the why. You may perceive and classify phenomena, but the ultimate underlying causes you can never know because the human mind is incapable of forming any conception of such causes. You may see and feel the effects of what is called matter by the manifestation through it of what is called force, but both matter and force are merely names for the unknown and the ⁱ sbsolutely unknowable. That these categories of existence are unknowable cannot, of course, be inferred from any knowledge of matter and force, since these are unknown; but from by a physiological one; the duration of life of the ferment the constitution of the human mind, which cannot conceive the ultimate causes which these categories, matter and force

Hence it concludes that human study and knowledge must lie wholly this side of matter and force; must concern itself wholly with relations, manifestations, or phenomena; while the *noumena*, the ultimate causes, must remain a sealed book

Now as all phenomena may be made the subject of demonstration it follows logically that this test must be dechange in the position of their atoms. Acetic acid is con- manded by all thinkers of this school, for the establishment of all the facts of science, before any inferences are allowable.

The positive philosophy maintains that whatever conflicts with our direct perception of relations cannot be admitted as true; as to conceive anything is to perceive clearly the relations it bears to other things, and the relations of its parts The formation and increase of the yeast plant is dependent to each other. Thus no man can believe at one o'clock upon the presence and absorption of nutritious matter that that at three o'clock it will be two hours earlier than at one rejected as false by any sane mind.

> But while the positive philosophy insists that fundamental facts shall be demonstrated (we use the term not in the mathematical sense) it does not exclude inferences from facts, or denythat there may be causes antecedent to all facts; it only denies the capacity of the mind to deal with such causes.

Finally, it makes a distinction between belief in the sense in which the term is most ordinarily employed, and knowledge, and as yeast consists in the main of a substance rich in nitro- but upon this point we cannot do better than to quote from the third lecture of Prof. Fiske:

> "A necessary truth is one of which the negation is inconceivable after all disturbing conditions have been elimnated. "A belief of which the negation is inconceivable is necessarily true, within the limits of human intelligence.

> "This test of inconceivability is the only ultimate test of truth which philosophy can accept as valid.

"By a singular freak of language, we use the word belief substances, and he also cites the labors of the best chemists to designate both the least persistent and the most persistent of Europe to show that his views of the action of yeast and coherence among our states of consciousness-to describe our leaven to produce fermentation is founded upon scientific state of mind with reference both to those propositions of the truth of which we are least certain and to those of the truth every element of theory and fact. It is so popular, not to say of which we are most certain. We apply it to states of mind which have nothing in common except that they cannot be justified by a chain of logical proofs. For example, you believe, perhaps, that all crows are black, but, being unable to furnish absolutely convincing demonstration of the proposiof Liebig's great paper must be looked upon as a timely pro-tion, you say that you believe it, not that you know it. You also believe in your own personal existence, of which, however, you can furnish no logical demonstration, simply because it is an ultimate fact in your consciousness which underlies and precedes all demonstration. So with the axioms of geometry. If asked what are our grounds for believing or to the materialistic doctrines of the so-called protoplastic that two straight lines cannot inclose a space, we can only reply that the counter proposition is inconceivable; that we The first part of Liebig's paper, which is all that has ap-i cannot frame the conception of two straight lines inclosing peared, is devoted to fermentation; the second portion is to a space; that in any attempt to do so the conception of Liebig has finally broken through the silence with which be occupied with the question of the origin of muscular force, straight lines disappears, and is replaced by the conception lieve it.

> "It is only in this latter sense in which the word belief is the controversy, if anything practical grows out of it. Λ | employed in the canon of truth above stated, and when Mr. passage at arms between such men as Liebig and Pasteur Spencer says that a given proposition is inconceivable he by no amount of effort be united in consciousness. Thus a proposition which, though utterly incredible, is not at all inconceivable; but that a certain triangle is round is an inconceivable proposition, for the conceptions of roundness and triangularity will destroy each other sooner than be united

in consciousness. And manifestly we can have no deeper
