

NEW YORK, MAY 6, 1848.
Bain's Electro Chemical Telegraph. Mr. Alexander Bain, the celebrated inven or of the Electric Clock, and many other inver.tions, has just paid a fying visit to this country to secure by patent his invention of the Electro Chemical Telegraph. He has been exhibiting his invention for a few days past in this city, and by invitation we exam ined his apparatus and received a full expla nation of the whole operation, both theoreti cally and practically from the inventor himself. The Electro Magnetic Telegraph as first contrived and now used in Europe and Ame rica is dependent, (as the name implies,) on Magnetism to move metallic bodies for the purpose of giving and recording signs, and as early as 1837 a Mr. Davy published in En glancs a mode of using the electric current to mark signs on cloth by chemical means, but his apparatus was only capable of giving about six signs a minute in a short distance by se veral wires at one point.
By the invention of Mr. Bain he dispenses with the magnetic action to produce mechani cal morements fo: making and recording of signs, and employs long strips of paper so perforated in groups that each group represents some known letter or sign. The nonconducting substance of the paper passing between the electrosed parts of the machine intercepts the electric circuit except at each perforation where the electrosed parts of the machine come in contact through each successive perforation, this admits the electric current to act with its natural velocity to comsplete the circuit and transmit the sign to a distant station where each sign is recorded by the electric pulsation passing into and through a chemically prepared paper made to revolve on a cylinder that travels at a like speed per minute as the perforated paper at the transmitting station. In this manner no time is lost by any mechanical movements or magne. tic action or by any manipulation of the operator at the machine and by multiplying the parts through which the perforated paper passes giving each part a separate battery and a wire to each line of telegraph, the same communication is fully and simultaneously transmitted to and recorded at any reasonable multiplicity of distant stations, or if a machine consisting of twenty such parts is re. quired to send to one, two or three distant stations only, all those parts not wanted are put out of action by simply turning back the parts that complete the electric circuit. In this manner Mr. Bain has transmitted signs representing one thousand letters (not words as has been erroneously supposed, per minute; and at the averase at $3 \frac{3}{2}$ letters to a word, this will be about 285 words per minute, but it is believed by Mr. Bain that he will be able shortly to transmit 3500 signs equal to 1000 words a minute, though he does not wish to assert that he has transmitted so large a number. No part of the machinery is liable to derangement, except the conducting wires, this is common to every other arrangement at present in use, though the time may rot be far distant when this last inconvenience may be a voided. By this mode of operation the public news of Europe or of the United States, may be composed in either country or on the passage between, so that on the arrival of the steamer the composed news may be at once placed in the Electric Telegraph, and in a few minutes be transmitted to every important place in the country, for the Press to be copying it for the public information in places hundreds and even thousands of miles apart within one hour of the same time at which it arrives; or a merchant having correspondence at a distantcity can use his own mode a agreed between himself and his correpondent of signifying letters by perforations, and in transmitting a notice by thismeans, be secur
concerns, because the paper containing the received and recorded notice going to the correspondent would only be understood by him and the party who sent it. And from the rapid action of this mode one wire will trans mit more than fitteen wires can do now, as so many communications can be successively sent in he sme time now occupied for Thi mode is in use between London and Birming. ham, a cistance of 112 miles, and between Manchester and Liverpool, a distance of 32 miles. It has been proved from London to Liverpool, a distance of 226 miles, nnder an unfavorable state of the tunnels through which the connection of the wires passed, but the result was the same, and when Mr. Bain left England the London and Liverpool line was in course of completion throughout.
We shall be able to present our readers with fine view of Mr. Bain's Telegraph, with description as to its operation, \&c. in a few weeks.

## Sclence and Labor.

There are many who suppose that scientific acquirements and a laborious occupation are incompatible things. There never was a greater mistake. If there is a single fact more strong than another to strengthen our proposition, it is that of our great New England Blacksmith, Elihu Burritt, charming and rivetting the attention of wondering listeners in the vast metropolis of the British em pire. Workingmen, just reflect for a moment upon the career of our blacksmith hero. A hort time ago we beheld him, the son of a widow, laboring at his anvil for his daily read. Now we behold him standing befure princes, the noblest priuce of them allprince of good works, noble thoughts, and a prince in eloquence and knowledge. How did Elihu attain to his present eminence? By the employment of his spare moments from hard labor in acquiring useful knowledge. There are many mechanics and laboring men who may not bave the advantages of Elihu Burrit, and many more have not his capacity, but there is not a single individual who makes the best use of all his privileges, a fact which too many have to regret when the circumstance of age or w orldly cares place such opportunities forever out of their reach. We speak now to young artisans and mechanics. We would sincerely call your attention to the ac quirement of what is useful when you are young. Remember that knowledge is never a burden to carry along with you wherever you go, but is rather a letter of introduction to th society of the sensible and the truly respect able in every land, while it is in a thousan ways serviceable in the pursuits of life. Far quharson who purchased Fontonwell Abbey was indebted for his wealth to but a very slight knowledge of chemistry, acquired in dependant of his profession. Ignorance on the other hand, is continually placing barri ers in the pathway of man's advancement We do not mean by "knowledge" that i should be acquired for the purpose of making money. Such an idea is degradatory to the character of man. Workingmen, for we are now speaking to you, should acquire useful knowledge for the very pleasure that is inherent in the acquirement of $1 t$, and for the object of being better men and better citizens There is no way by whick the working peo ple will ever be elevated to a higher position in society, than by sound knowledge-"knowledge is power." When men intelligently understand themselves-their own rights and the equal rights of others, then they will exer an influence at once healthy and beneficia both for their own benefit and the benefit society. This kınd of spirit is now being de eloped and these opinions are now bein xtended among the working classes through out many parts of the world. With a calm and solii judgment they perceive that virtue common sense, correct information, and calm and liberal views are the only true guides tor the elevation of any class of men, and cer tainly these vieurs and these acquirements are not incompatible with Labor.

The Pensacola Gazette describes the Arca dia Cotton Factory, near Pensacola, which is now in succeessful operatian It is worked entirely by slave labor, runs 25 looms, and urns out one thousand yards of cotton per
ny of Power in Cotton Fact
(Continued from our last.)
Considerable difference of opinion exist respecting the best bush metal for shafte to turn upon, aud though of the first importance there is no point connected with the construc tion of machinery so scantily furnished with satisfactory experimental data.
James Ferguson, and other scientific men, having investigated this subject, recommend the metal composed of the most minute particles.
As friction results principally from ine qualities on the surface of bodies coming in contact with each other, they very plausibly conclude (and experiments upona small scale without the use of any lubricating substance seems to bear them out,) that fing grained metals presenting tewer inequalities on their surface cause less friction. This theory, howe ver, does not seem to stand the test of expe rience on a large scale; indeed the whole subject of friction is involved in mystery.All writers that I have consulted with the view of obtaining definite ideas respecting it, either express themselves with extreme cautıon, or deal in vague generalities. Castıron properly hardened, has answered a better purpose for shaft beariags than ans thing I have ever used. If it is well oiled the first month of its being used, a fine skın enamel is formed on its surtace, which with the same quantity and quality of lubricating matter, will allow large shafting to revolve more freely than the finest brass or composition in common use. If, however, from neglect it is almon use. If, however, from neglect it is al-
lowed to run dry until the metal wears, it is more apt to do so again, hence no agent of a cotton factory should leave the entire care of the shafting in subordinate hands during the irst month at least of its operation. Ofcourse we would not recommend the agent to apply the lubricating matter himselt, but we do not think it would derogate from the dignity of his station, or permanently injure his finers to apply them occasionally to the bearings to satisfy himself that they do not " heat." This may be reckoned among the " meaner hings" that ought to be left "to low ambition," but we consider no man capable of staring up a new mill with profit to the owners, in a place where manufactories are not al eady in successful operation) who is not wiling to attend personally to every minutia until a proper system is established, and overseers, whose integrity and ability may be implicitly relied upon, are put in charge of the everal departments.
Should any bearing wear so much as to prevent the shaft running true, it ought to be re placed by a new one at once,-if however, the surface is merely worn rough, its polish may be restored by applying brimstone mixed with oil, a few days while the shaft is in operation. When the oil is used for lubrication the best sperm the market affords is the most economical to use in a cotton mill. For shafting not over three inches in diameter, nor re volving moie than 120 turns per minute, it answers well, for satety and economy, to have a hole about an inch square in the cap direct ly over the bearing, and kept constantly supplied with common tallow which being al ways in contact with the revolving shaft, 1 needs no other lubrication, unless the tallow is unusually hard, then a few drops of lubri cating oil may be poured upon it once a week As there is more danger to be apprehende from large slafting heating in the bearing the Lubricator should always be applied.

the lubricator
This consists of a tin cup, capable of holding about a pint of oil, with a small tube passing through the bottom and reaching nearly to the top inside. It should be placed sothat the lower end of the tube will point to the centre of the bearing; if the cup is filled with oil and sup plied with a wick, one end of which resting
in the oil and the other passing down through
the tube to the bearing, capillary attraction (the same principle that supplies combustion in the common lamp) will cause a constant dripping of oil from the wick, proportioned to its length and size. Any contrivance to raise the wick from the oil, or press upon $\mathrm{i}^{\mathrm{t}}$ at the top of the tube will stop its capillary action when the shaft is not in operation.The Lubricator should be applied to every earing liable to heat from excessive friction.
W. Montgomery

## American Carriages.

Two handsome omnibusses have arrived in Philadelphia from Troy, N. Y., of which the Ledger speaks in terms of the highest praise The one is called General Taylor and the other Eclipse. Thes are said to exhibit a high degree of workmanship. The painting is heau ifully done and the ornamental gilding and scroll work which the sides of each present as well as the lettering, is of the most beau tifal description. The interior of the coaches is furnished with crimson velvet cushions, of very superior make, while the sides are embellished with strips of highly polished mahogany Each coach has been provided with a burning fluid lamp in front, to which has been added an improvement, consisting of tubes to carry off the smoke. Such specimens of mechanical skill exhibits the great perfection which the artisans of our country have reached in the manufacture of convey ances for the ease and convenience of the pub lic. A number of very elegant light carria ges were shipped from this city to London last Fall and met with high commendation and a ready sale.
Cotion Ralsing and Cotton SpinaingA correspondent writing to the Alabama Planter, says:-
"Cotton raising is a rather uncertain and unprofitable calling. It is a little like gold digging, delusive: yet I do not know what else to engage in, unless I build a factory. I have water power near at hand sufficient to drive one or two thousand spindles. From what I can learn, manufacturing cotton is far more profitable than raising it. In fact, if a house with which I have correspondence, makes correct statements, a factory costing 15 to 20,000 dollars would pay for itself in twelve or eighteen months. If you can send me a partner with funds, I should be tempted to try the experiment."

Herman Steamer, at Halifax.
When the Herman put into Halifax, she was visited by Sir John Harvev, the Gov'r., accompanied by lady Harvey, the provincial Secretary, and a number of army officers. The boom of a gun saluted his Excellency on boarding her, and the vessel in honor of the occasion, was decorated with gay flags. Sir John was most graciously received, and after examining the different departments of the examining the different departments of the
steamer, partook of a Luncheon in the saloon. On leaving, he was pleased to express the entire satisfaction and extreme pleasure he received from his visit
Sclentifie American--Bound Volumes. The second volume of the Scientific Ameican, bound in a superb manner, containing 416 pages choice reading matter, a list of all the patents granted atthe United States Patent Office during the year, and illustrated with over 300 beautiful descriptive engravings of new and improved machines, for sale at this office-Price ${ }^{\$ 2} 2,75$. The volume may also be had in sheets, in suitable form for mailingat $\$ 2$.
The back Nos, of the present volume may also be had upon application at the office.
