Scientific American.

It is invariably the case that after science has given birth to a new art and nurtured it for a while, that it passes over to the industrial world, where it is baptized in a new name, clothed in a new garb, and set to work. Here the scientific world loses sight of it; all future improvements remain with the artizan. Science feels the alienation and can no longer even correctly describe its offspring ;--that which was an experiment of the laboratory or the lecture table, has become a trade.

Electro metallurgy has been described in almost every paper published in the country, and there is not, perhaps, even a village where silvering and gilding has not been attempted by ingenious persons, but it has always failed termed galvanizing. This has been because chemists describe an immatured art, in language which one professor of chemistry would use in speaking of another; or the general principles alone were treated of, and scientific technicalities profusely offered in the place of experience.

The electro arts are yet in their infancy, and their importance is but beginning to be appreciated. Silver is the only metal suitable for macan be made of a metal superior to silver in mechanical properties, and kept plated with pure silver for less than the interest of the money they would cost if made of silver; and the facility with 'which electro-plating is exeproducing them. Articles greatly excelling in boldness of design and grace of execution, the labering classes an opportunity to possess some specimen of artistic skill to grace the festive board or garnish the picture of home.

The voltaic precipitation of copper is of great importance, for the voltaic metal is not as liable to corrode as the ordinary metal. Culinary articles formed of it must soon take the place of the wretched tin pans, now so generally found in the kitchen. It is highly probable that steam boilers formed of it would not be liable to incrustation, and, from noncorrosion, would last many times longer than those made from impure copper.

The formation of coin from voltaic metal would have such advantages that our government should no longer make cents from any other, for this is the coin generally found in the hands of children, and is handled more, perhaps, than any other; it is constantly gathering a coating of poisonous matter, which readily adheres to the fingers; children frequently put these coins in their mouths, and death has not unfrequently ensued. Cents made of voltaic metal would always remain clean.

The electrotype art is, however, rapidly rising to importance, and its advantages being have required as much as three years to produce them, are now coming into use; it is known that 1,000 prints from one such plate, if the work is delicate, will wear it out; if the plate has cost \$5,000, the 1,000 prints must pay this between them: this would be an insuperable obstacle to this kind of engraving, by the electrotype art, and thus any number of depth than the main pit. prints obtained, without using the original

The art of electro-gilding consists in depo-In the article on Gilding will be given infallible directions for preventing the occurrence of the black deposit, and producing firm adhesion; directions will also be given for producing firm adhesion between the basis and deposited silver, and a method described of making pure cyanide of silver and potassum, free from admixture of potash or its acid salts.

VOLTA.

Compressed Air Engine.

The following is a description of a "Compressed Air Engine," employed near Glasgow, taken from the "Daily Mail" of that city, which is celebrated for manufactures and engineering. The engine is employed in a coal except to bring an outcry against what is pit of Messrs. Allen & Man, at Little Govan, from the top of the pump cylinder, are each near Glasgow :

> "The compressed air is only employed on this occasion as the most convenient form of transmitting power to a great distance and at a great depth, under ground; and not as a merely economic mode of obtaining or generating power.

The objectsought and so successfully applied in the present instance, is the working of winding engines, placed at a depth of nearly ny table articles, but it is too scarce to be em- | 100 fathoms under ground, and at a distance ployed generally for this use; but the articles of about half a mile from the pit-mouth, where the steam engine is fixed.

To work an ordinary steam engine at such a depth, and in a remote part of the mine, would be next to impossible and highly dangerous, owing to the inflammable gases in concuted, has entirely changed the method of stant course of extrication from the workings, which might at any time explode by coming in contact with the furnace fires of the boiler. have been so cheapened, that it gives even to Besides, pure air is too valuable down in the galleries and workings of a pit, to have it destroyed or contaminated by the results of combustion from a large steam engine furnace.

> Many attempts have been made on the continent and elsewhere to transmit power from a convenient prime mover to long distances, by means of pipes; but the principle almost always adopted was that of exhaustion. Where the distance was great, the result was next to nothing; and even within certain limits, the inward leakage of the pipes in a great measure destroyed the effect of the vacuum obtained by the prime mover.

> Another mode is, by employing the pressure of a column of water, instead of steam or compressed air; but the want of elasticity in that fluid operates injuriously upon the working machinery.

It was these considerations which induced the engineers to devise the present most successful effort at overcoming difficulties, hitherto deemed nearly insurmountable.

The apparatus may be divided into two parts-first, the prime mover, which is a noncondensing steam engine, above ground, at the pit-mouth, working two air-pumps for compressappreciated; large engraved plates, which ing the air; and second, the winding-engine, some 600 feet below the surface, and half a mile away, which receives its power from above ground.

The latter is, in all its parts and details, precisely like a non-condensing steam engine, but only actuated by compressed air, instead of steam. This engine is employed in winding but the plate can be multiplied to any extent the coals from workings at a still lower

The column on which the bearing of the walking beam is fixed is hollow, and forms a receptacle for the condensed air before it passair-pump.

Each air-pump is single-acting, compressing the air only during the upward stroke, and forcing it into the great centre column or airchamber. Instead of any of the ordinary forms of valve, the engineers designed an extremely simple but effective application of the spherical or ball valve. The nump cover, the piston, and a diaphragm, which is placed a few inches perforated with about fifty circular holes, an inch and a half in diameter. In each of these holes a ball rests, ground to fit water-tight, and all opening upwards. As, however, it is of great importance that every inch of compressed air should be ejected at every stroke of the pump, an arrangement is contrived by which a quantity of water, more than equal to the necessary clearance between the piston and the ends of the cylinder, always rests upon the piston, the diaphragm, and the cover-so that and if there is any overplus of water, it finds its way, along with the air, through the airport into the air-chamber, whence it is forced by the pressure of the condensed air, through a small pipe, back to the piston, during the return stroke. The air is condensed to a pressure are sufficient to keep it at work for several minutes : but the engine man takes care that and as soonas it begins to blow off from a safetyvalve in the engine-room, the pumping is discontinued. The air-pipe is ten inches diameter, and, passing down the shaft, is carried along a horizontal gallery for half a mile, until it is connected with the winding-engine; but mine extends in the new workings."

This engine was constructed by Messrs. Randolph, Elliott & Co., engineers, Glasgow. solid rock, 600 feet distant from the pit bot-

We shall have a trial of a kindred character by-and-bye : - six persons were killed on the Edinburgh and Glasgow Railway, in consequence of some delay in running trains down the declined tunnel into Glasgow ; the second es into the exit-pipe; and there are two large part of the Perth train ran into the first. I ports connecting it with the upper part of each | am told that the second train ran in only at the rate of 3 or 4 miles per hour, but could not be entirely stopped in time. A train going at the rate of 30 miles per hour cannot be stop. ped by the ordinary appliances under 400 wards. In this case the train had not been running at 20 miles per hour, and although slowed considerably, was still moving from 3 to 4 miles when the engine struck the preceding carriage. I believe the signal men are to blame.

Considerable hopes are entertained here of the finest quality of cotton being cultivated in Ceylon. It is found to grow better there than in any other part of the East. The price of cotton in the Deccan is not over 1d., and 14d. the lb. At Port Natal, the few bales hitherto prepared, have not brought over 2d. on the spot; the quality was good, and sold in England for 6d., 7d. and 8d. A company is going to advance money for the purchase of cotton on all the west coast of Africa, where it is inevery particle of air is expelled at each stroke; digenous and grows wild. Some speculations exist respecting the probability of growing it in Asia Minor and you will soon hear of cotton plantations on the Euphrates and Tigris.

The imports to London, from India, during a period from January to 1st September last, for the past and present year, have been 69.680 of 30 lbs. on the inch; and the contents of the bales in 1849, in 1850 172,200 bales-increase pipes, extending to the winding-engine, below, [102, 520 bales. But the greatest rise was in the four last months, and I should not be surprised to find, before the first of January 1851. the pressure is always keptup in the air-pipes; an advance of 150,000 to 200,000 bales on the quantity received in 1849-a matter of small importance at first sight, but one which makes a great difference as to price.

The Egyptian yield of corn and cotton is remarkably good for the season.
