NEW YORK, MAY 10, 1851.

Cannel Coal of Virginia.

We have now before us a beautiful specimen of the Cannel Coal of Kanawha, Va., and as our acquaintance with this kind of fuel is not inconsiderable, we have no hesitation in saying we believe it to be equal to any coal of of purposes. Cannel Coal breaks with a dull fracture, but is capable of receiving a polish like marble, and it can be worked with a knife tiful ornaments made of it, and in a foreign paper, we recently noticed that a sofa had been made by a Scottish miner, for the Great Exhibition, out of this material. But beauhard, yet pliable grain, its value consists in its usefulness and superiority, as an article of fuel and a producer of light and heat. No coal can equal it for producing gas, either in quantity or quality, and this is a fact to which we hope some attention will be paid by our gas companies. It is stated to be better than the Cumberland coal of Maryland for raising steam, and is free from any liability to spontaneous combustion. Those bituminous coals which are liable to spontaneous combustion, contain a considerable portion of sulphur; this is the reason why they generate so much heat when packed together, and made wet with wa-

If one part of water is added to six parts of strong sulphuric acid in a glass vessel, the liquid will be raised to nearly the boiling point. gases in the coal, and a spark will do the rest to set the whole on fire. It is not long since we gave an account of three vessels being burned by the spontaneous combustion of the coals which formed part of their cargoes. It is the absence of sulphur in cannel coal. which makes it so valuable for good gas. We would like to see more of this coal in our city, and hope that we may induce some to use it for domestic purposes. It burns in a grate like a candle, with a fine white flame, and leaves only a few white ashes behind. The coal fields of America are of greater extent than those of all the world beside. We have anthracite, bituminous, and cannel coals in abundance. Our people in New York know what the Liverpool and Pennsylvania coals are-bituminous and anthracite, but few, very few of them know anything about the beautiful cannelcoal; not one in a thousand, we believe, has ever seen a sample of it. We trust that what we have said may be the means of bringing it more prominently into public no-

Anhydrous Steam---" Stame."

It is well known to our readers that Mr. James Frost, engineer, of Brooklyn, has pubdition of 40 of heat. This new property he alternate stroke, consequently has less cooling denominates stame. All the chemists and en-Dalton, assert "it requires 4800 to double the Haycraft recommends a steam jacket to be apvolume of steam." It will be observed, if 40 plied to all locomotives especially. nis pamphlet to the bridge, Mass., who, through Prof. Horsford, replied through our columns, as we had published the said report. We have always had a great respect for the statements of Prof.

lished his views in the London Mechanics' Magazine, in reply to Mr. Frost's pamphlet, which was also published in that periodical. He speaks with great respect of Mr. Frost's molecules). experiments, but he does not coincide with his ideas of the doubling of the volume of steam by an increase of 40.

Twenty years ago he entertained nearly the same views as Mr. Frost, and had a small steam engine constructed of a 4 inch cylinder, the same kind in the world, and far superior jacket was furnished with steam from a high to any other coal whatever for a great number pressure boiler. On working the engine with for the principal kingdoms of Europe, and common steam, it required 85 revolutions to fill a given measure with condensed steam, but on applying steam of 500 lbs. pressure to or chisel into any form. We have seen beau- | the steam jacket, it required 920 revolutions to | discovery to his fine new steamers, was not fill the same measure—a very great saving, as any of our readers will see, for the engine in both cases carried the same weight. From tiful though this fuel is, with its clean and anhydrous steam-the stame of Mr. Frostwas ten times more economical than common moist steam. He afterwards had a large enthe parts soon gave way; however, it confirmed him for a time in his former opinions It occurred to him, one day, to make a calcu. lation of the actual working of his engine, when he was astonished to find that his stame posing it to have the rarity of Watt-1728 times greater than water. On examining lation. To prove whether there was a loss by escape of steam in a well-constructed engine. or a great increase of volume by super-heating This generates the carbonic and hydrogen it, Dr. Haycraft filled a graduated tube with mercury, closing one end and introducing into a part of it oxygen and hydrogen, in the same proportions in which they form water. These gases he detonated by wires and reduced them to water. The whole was placed in an oil bath, which was gradually heated to 2100, when steam was formed, filling the tube to a marked point. On this a calculation was made, which proved it to be increased in vopoint, he began to increase the temperature of the oil to test the theory of Dalton, viz., that it required 4800 of extra heat to double the tonishing number of 3,650,000 in a year. If volume of steam. He increased the temperature to 360°, all that his tube could bear, when he found that it made no sensible increase in the volume of steam. This experisame result. This is at variance with Mr. will do more work in the same time, by torch-Frost's experiments. He believes that Mr. Frost's tubes were moist on the interior surface, and that this moisture was not taken into account in calculating the quantity of experimental common steam.

Dr. Haycraft believes that the loss in common engines is attributable to a cooling in mon Council try an experiment—a fair expethe interior of the cylinder every stroke of exhaustion; James Watt had a glimpse of this lished a pamphlet wherein it is stated—and | idea himself, when he applied the steam jackthe method of performing the experiment is et, and according to Mr. Frost the steam enillustrated-that when steam is heated apart gine has even retrograded since Watt's day. from water, it is doubled in volume by an ad-! converted into stame. Dr. Haycroft believes | progress of improvements in the arts unless he of anhydrous steam (steam free from watery

In the last number, (April 12th) of the London Mechanics' Magazine, Mr. Frost has 40 of heat doubles the volume of steam and changes it into "stame." We have been intubular condenser, and steam jacket. The formed that Prof. Stevens of the New York University, purchased the patent of Mr. Frost that Mr. Collins purchased part of the Engish, if not the whole of it, and has stated that the reason why he did not apply Mr. Frost's owing to his disbelief in its merits, but because, he said, (as we have been told, but we do not give it as on our own authothis experiment he was induced to believe that rity), "if it were applied, it would enable small capitalists to compete with large ones in steam navigation." This opinion is contrary to what we would expect. and we are ingine built with a fire around the cylinder, but clined to believe that there must be some mistake about it.

Paving Streets by Torch Light. Why don't our Street Commissioners get the cobble stone pavements repaired by torch was just about equal to what it should be, sup- light? Let a section be taken up and completely laid down by morning, and do not let a single stone be touched during the hours bethis he recollected a remarkable admission of tween 10 A. M. and 6 P. M. It is confusion that greatest of engineers, (Watt) that, in his | confounded in our streets whilst being repairbest engines, there was a consumption of ed, (and when are they not) for whole lines steam double of what was required by calcu- of stages, like moving caravans, have to turn abrupt angles, and deploy out of line hundreds of times in one day, all owing to twenty or thirty men digging and driving away at the repairing of some small piece of pavement. The streets never need be obstructed on this account, and thus thousands, by tear and wear, in making long circuits and losing time, would be saved to the citizens every year. It may be said that this would be more expensive to the city. It would not; it would be a great saving, for every mile a carriage is saved in travelling so is there less wear of pavement, and who can doubt but 10,000 vehicles have to lume about 1728. Having ascertained this travel, every day, more than one mile each out of their direct routes, by obstructions in the repairing of streets. This amounts to the aswe take the half of this, we have nearly two millions of miles of unnecessary travel, and the time lost is incalculable. Plenty of men can be found who will work at night, if paid ment was repeated several times with the fair wages; and we venture to say that they light, than they can by sun light. Why? because they have to be continually on the lookout for horses prancing up to the flanks of their barricades. Their work is generally hurried and miserably done—it certainly could not be performed worse blindfolded. Let the Comriment, and with perseverance they would soon come to the conclusion that our streets can be kept in better repair, never be obstructed, and city funds will be saved by adopting the plan of paving our streets (for repairs only, we mean,) by torch-light.

Thaver's Bridge.

Mr. George W. Thayer, of Springfield, Mass. called upon us last week, on his way to North Carolina, to erect one of the Bridges which bear his name, with a span of 200 feet, on both at home and in England, is now in the the great discovery of the age. Mr. Frost sub- of engines is priming—the carrying up of a the line of the Wilmington and Weldon Rail- Holy Land. He was wrecked on the Nile by road. Mr. Thayer has put up one of his bridalong with the steam. Dr. Haycraft recom- ges on the Georgia Railroad, and it gives reported against its correctness, and Mr. Frost mends the strictest attention being paid to universal satisfaction to the engineers. We sketch-book and drawings were saved, and published an illustrated description of Mr. Thayer's bridge on page 190, Vol. 2, Scientific of Americans were along with him, and were We must say, along with him, that this American. Since that period many improved very kind. The Rev. Dr. Scott, of New Or-

that stame is only what is known by the name | takes a paper devoted to the propagation and discussion of science and art. There is scarcely a day passes over our heads but we have to refer to the back pages of our paper, to show that such and such a thing has been described a reply to Dr. Haycraft, but it does not touch by us before. We have, in a number of cases, the main points of this new theory, viz., that had to refer to Mr. Thayer's bridge, as embracing the principle of what an inventor considered something new. One man, after he had spent about two years on an improvement in boiler feeders, came on to New York with his model, and after showing it to us, we pointed out its homologue in Vol, 2 of our paper. He declared it would have saved him \$400 if he had been a subscriber to it from its origin.

Light Locomotives.

We learn by the "South Boston Gazette" that Mr. Seth Wilmarth, of the Union Works, in that place, has built a locomotive which only weighs eight tons, for the Cumberland Valley Railroad. The boiler is 9 5-12 feet in length, and 2 3-12 feet in diameter. The cylinder is 84 inches in diameter with a stroke of 14 inches. The heating surface of the firebox is 13 square feet, the heating surface of the tubes is 190 square feet. There are 64 tubes, each 7 feet in length, and 12 inches in diameter. The locomotive and tender form a part of the same frame, the tank being capable of holding 400 gallons, the boiler, 168 gallons. The whole length of the locomotive is 18 feet, which is placed upon a pair of leading wheels 30 inches in diameter, a pair of trail wheels of the same dimensions, and a pair of driving wheels 43 feet in diameter. It has been used on the Brookline branch of the Worcester Railroad, much to the satisfaction, it is stated, of the engineers, and Mr. Wilmarth has entered into contracts to build two more of the same size. For branch railroads, on which there are but light trains, it is folly to employ heavy engines, but the grand point is to hit the weight suitable for the work to be done. Engineers in America and Europe are now giving this part of engineering great attention, but certainly no more than it de-

Electrotyping --- Our New Heading.

The heading of the "Scientific Ameri-CAN," this week, is a specimen of the progress of science. Hitherto types were either cast or carved, but the "heading" spoken of was performed by the same element as the lightning which cleaves the oak of the forest, and shatters the mast of many a gallant ship. The characters are of copper done by the electrotype process, by Mr. J. W. Wilcox, of Poston, who has been engaged in the business for the last five years, and has perfected the art so that it is no longer an experiment, but one of the "fixed facts" of science. Duplicates of wood-cuts, copper plates, type, &c., are warranted perfect, and copies of wood-cuts print as well as the wood itself, while they last ten times longer than either wood or types. It is a splendid art for the stamps used in cotton factories and bleaching establishments.

This is an art of very extensive application. It is very useful but it requires great skill and practice to be master of it. Those who desire copies of figures in hard enduring metal, Mr. Wilcox is the man to perform the work desired n the very best manner.

Banvard, the American Artist.

John Banvard, the artist, whose Panorama of the Mississippi excited so much attention a real African Simoon. He lost his gold w and all his money, but luckily, he says, his this made him forget all the rest. A number kind to him, they being one mile ahead and When we take a retrospective view of the in a place of safety, came to the rescue with
