NEW YORK, MAY 24, 1851.

Young Mechanics The Way to Rise. We stated last week that few of our mechanics rose direct from the workshop to important places of trust in the Republic, and we also stated that but a few of the great many were qualified to fill important situations even in connection with the trades they learned Why is this? Is it not possible formen to be as well educated in the workshop as anywhere else? Do mechanics not possess the same abilities as those who follow the professions ? Yes. Well then, why is it they are not in general fit to march out from the workshop to fill the highest and most honorable offices in our country?

The answer is, they do not in general try to qualify themselves to fulfill their proper duties, as citizens of this great Republic. We suppose that our mechanics themselves would be planet-struck, if it was proposed to run one of their number for President, but it is not our object, except in an angular direction, to point to political situations-we hope the point however, will not be lost.

We have alluded to the absence of a taste for sound and solid reading among our mechanics, and we have now to complain of the absence of a pure and lofty conversation. The majority of our young men belong to fire or military companies, and during their spare moments, their conversation consists more in what this and that engine cap do, &c., and not about how it can be done. Idle, vain and frivolous conversation has a very injurious tendency, like reading bad books. A pure conversation and gentlemanly discussion of useful questions, has a very elevating tendency. Young mechanics, we speak to you, in all earnestness; if you wish to rise, you must be enthusiastic about your business, and in the pursuit of knowledge connected with it. In your spare moments, endeavor to seek enjoyment in talking about the principles of your trades, seek to know the why and the wherefore of everything connected with them, and whatever your hand findeth to do, do it well and with all your might. Do not be eye servants, do not use profane language, and give yourselves the best education you possibly can Every machinist should learn to draw, so should every carpenter, and do not be content until you fully understand, and can construct every machine, apparatus, or whatever it may be, and can take charge of and superintend every branch of business connected with your trades. Men possessing such qualifications are sure to rise. And what is to hinder you from possessing such qualities, along with a character for honesty, fidelity, and ability? Let every one put this question to his own heart.

New Theory of the Central Heat of the Earth and the Cause of Volcanoes.

Mr. Stevenson Macadam, of Edinburgh In South-Western Georgia and all that rea machine upon the same principle. In 1836 | 12,672 lbs. Scotland, has advanced a new theory, as indigion of country beyond Macon, as well as in We have no data of the battery expense of Mr. Davenport propelled a turning lathe with cated by the caption of this article, which the north-eastern counties lying on the Savanthe locomotive of Prof. Page, but the experihis electric engine, and at the same time Mr. puts an entire new face on the subject, and is han river, the plant is small and unhealthy. ments of Mr. Hunt and others have proved Davidson, in Scotland, had a turning lathe distinguished by the firm, clear, unmistakeable The same is true of Burke and Jefferson, that one grain of coal consumed in the furand a small locomotive in operation by the logic of the Scottish School. It is well known two of the most productive counties in the nace of a Cornish engine lifted 143 pounds same power. In 1838 Prof. Jacobi applied that as we descend towards the centre of the State. The cold weather has kept the one foot high ; whereas one grain of zinc conhis electro-magnetic engine to propel a boat at earth (for all the small depth yet penetrated). plant from coming up, and consequently the the temperature increases at the rate of about St. Petersburg ; and the effort was apparently sumed in the battery, lifted only 60 lbs. stand is a poor one. In no particular, is the The difference of expense between steam a very successful one, for the boat had padone degree every 45 feet. Proceeding to reason prospect so good as it was at this time last and electro-magnetism is obvious, the latter is upon this as a basis, many suppose the centre dles, was 28 feet long, 71 wide, drew 21 feet year. It will require favorable seasons and a of the earth to be a red hot fluid mass, and of water, and with only a battery of 64 pla. fifty times more expensive, and some new dislate fall to make so large a crop as the last. they account for volcanoes and hot boiling tina plates, and but a small engine, he procovery in its chemical developement must be springs upon this theory. Southgate Smith, public attention to this "beautiful, cheap, than water in this spheroidal state. It is of Ohio; Wm. C. Langdon, of Kentucky; Tiand all those we have seen, exhibited, acfound that there is no real contact between and simple power," as it was termed. In New these spheroids of water and the red hot me. York, about 1841, electro-magnetic engines becording to their size, had far less power than mothy Fitch, of New York, and Henry Baldtal, but a kind of reflecting atmosphere of heat. | came a kind of mania, and hundreds were ma- | the common steam engine. win, of Tennessee, at a salary of \$1,500 each.

Mr. Macadam believes the crust of our globe nufactured to meet the market demand. It at the centre of our planet, in the same way that the spheroid lies on a red-hot plate. The internal crust he likens to a concave mirror, and the hotfluid mass to a sphere, with an atmosphere between the two of vaporized metal. He believes this heat is constant, and that the crust of the globe is influenced by two great forces-gravitation and spheroidal repulsion.

As it regards volcances, he believes they are aused by basins of metal at a high temperature, to which water finds admission, thus generating steam, which causes volcanic explosions in some cases, and hot springs in others. The volcanic theory is thus set down as caused by chemical action, the central heat theory has nothing to do with chemical action.

These are the principal features of his theo ry, and it may be true and it may not. Among the many new and useful discoveries which are continually being developed, there is much that is speculative and of no real earthly be. nefit-speculationswhich can never be settled, consequently any person has the perfect right to be as wild and extravagant, or plausible, as he chooses, there being no risk to run, while there may be considerable notoriety gained. This theory of Macadam, however, is the most plausible on the subject which has yet been advanced, we think; and as he allows us 25 miles of solid crust, after which all is red hot fire, we may consider ourselves on solid floating ground until some better theory is advanced.

- - - -Electro-Magnetism as a Prime Mover.

Although much has been recently said and written about the application of electro-magnetism as a prime mover, it is not a new subject by any means. After the discovery of Electro-Magnetism, by Oersted, in 1819, it at once became apparent that a uew mechanical power was given to man, and many were enthusiastic about its superior advantages over steam, as a propelling power. Our own Professor Henry, now of the Smithsonian Institute, first demonstrated the method of developing great magnetic power in soft iron by a small battery, and as a natural result he applled it to propel machinery. In 1831 he described, in Silliman's Journal, a machine for producing a reciprocating motion, "by a power never hefore applied in mechanics-by mag. netic attraction and repulsion." He stated, however, that it was no more than a philoso. phical toy, but deemed it not impossible that a modification of it might be applied to some useful purpose. In 1833, Dr. Schultless, of Zurich, Switzerland, exhibited a machine propelled by this power, and sodid Dr. Ritchie, of London. In 1834, Prof. Jacobi, of St. Petersburg, described to the Academy of Sciences, in Paris, a method of propelling machinery by electro-magnetism; and, about the same time, Mr. Davenport, of Vermont, who has corresponded with the Scientific American, contrived

to be lying upon the interior red hot round sea did not last very long, however : it was found prime motors, and we have no hopes of ever that they were expensive, weak of power, inefficient, and troublesome. In 1842, Mr. Robert Davidson, of Aberdeen, Scotland, (a mechanic like our Mr. Davenport), built a locomotive weighing five tons, and experimented with it on the Edinburgh and Glasgow Railway. He had 6 batteries, in all containing 60 zinc plates, with iron ones intervening. Th carriage ran at the rate of 4 miles per hour-a failure, to be sure, as we stated last week. The experiments of Jacobi, Davenport, and Davidson, caused disappointment; still, many attributed their failures to mechanical and other defects, and not to the inherent nature of electro-magnetism. This is the right spirit, for, until all the depths and shoals of this science are discovered, it is folly to despair. Among the many successful investigators and experimenters in Electro Magnetic science, the name of Prof. Page stands high; and his recent experiment with an electro magnetic locomotive at Washington, is the greatest effort of the kind ever made. It makes no matter how much mechanical power may be developed by electro-magnetism, if that power is derived at too great an expense to compete with steam , and it is our opinion that the economy of steam power is not so well understood as it should be by many who are sincerely laboring to perfect electro-magnetism. Hunt, in his experiments, says he proved that the greatest amount of magnetic power is produced when the chemical action is most rapid. Hence, in all magnetic machines, it is more economical to employ a battery under an intense action, than one in which the chemical action is slow. It has been proved by Mr. Joule that one horse-power is obtainable in an electro-magnetic engine, the most favorably constructed to prevent loss of power, at the cost of forty-five pounds of zinc, in a Grove's battery, in 24 hours; while seventy-five pounds are consumed in the same time to produce the same power in a battery of Daniell's construction.

A voltaic current, produced by the chemical disturbance of the elements of any battery, no matter what its form may be, is capable of producing, by induction, a magnetic force, this magnetic force being always in an exact ratio to the amount of matter, (zinc, iron, or otherwise) consumed in the battery.

What amount of magnetic power can be obtained from an equivalent of any material consumed? The following were regarded as the most satisfactory results yet obtained :

1. The force of voltaic current being equal to 678, the number of grains of zinc destroyed per hour was 151, which raised 9,000 pounds one foot high in that time.

2. The force of current being, relatively, grains, which raised 10,030 pounds through the space of one foot.

3. The force being 1,000, the zinc consumed was 223 grains; the weight lifted one foot

We consider the locomotive the prince of seeing it superseded by an electro-magnetic engine. We may be mistaken, but when 400 tons can be drawn 58 miles at the expense of only 14 cents per ton for coal. as has been done by a locomotive, we may begin to talk of the importance of Electro Magnetism as a prime mover.

Astronomical Observations at Washington. The second volume of "Astronomical Observations," made under the direction of Lieut. Maury, at the National Observatory, Washington, containing the Appendix, has just been published. It is a work which does honor to our country, and Lieut. Maury has our thanks, and will have that of all our readers, for the information we are permitted to glean from its pages in relation to the Electric Clock of Dr. Locke, &c. Capt. Wilkes, of the Navy, it is stated, was the first to apply the magnetic telegraph to the determination of longitude. This was done five or six years ago, for determining the difference of longitude between Washington and Baltimore, and he reduced the results down to the accuracy with which the time, between the ticks of the second-hand could be measured by the eye and the ear; this was the first time the magnetic telegraph was reduced to a valuable astronomical instrument. In 1848, Dr. Locke, of Cincinnati, informed Lieut. Maury that he had invented a Telegraphic Register Clock for Longitude. This clock has been erected in the "National Observatory," by Dr. Locke, and the principle of its operation is the breaking and closing of the circuit, so as to make regular marks on a fillet of paper of a certain length, to indicate the 100ths of a second, unless the circuit is broken by the operator, who is observing the heavens, noting the transit of stars. He then lays his finger on the key, breaks the circuit, and, during the time the circuit is open, there is left a blank on the paper, which can be measured by compasses, and will tell whether the blank was 100th or has second-time of transit.

- - - > - - - -Pay Your Postage.

When any person sends a letter to another upon matters of business, to gain information, he, as a gentleman, should pay the postage. Mr. O. Child, of Illinois, whose Saw Mill was illustrated, in No. 26, who was made to reside in Ohio, by mistake, has received a number of letters for which he has had to pay double postage. We believe that but few realize the extent of our circulation; when any machine is illustrated in our columns, if it has any merit, it is sure to meet with great attention, and hundreds of letters are sent to the proprietor; in such cases it is no more than just and fair for correspondents to pay their own letters. 1300, the zinc destroyed in an hour was 291 Those who wish to write to Mr. Child will be pleased to direct letters to Granville, Illinois, -not Ohio.
