\$3.00 A YEAR.

THE NEW STEEL FLOATING DERRICK AT THE BROOKLYN NAVY YARD.

We illustrate herewith a new steel derrick of great lifting power, recently constructed for the United States Navy Yard, Brooklyn, N. Y. It was built by the Pusey & Jones Ship Building Company. Its calculated and allowed lifting power is 75 tons, making it rank among the most powerful of the floating derricks in this harbor.

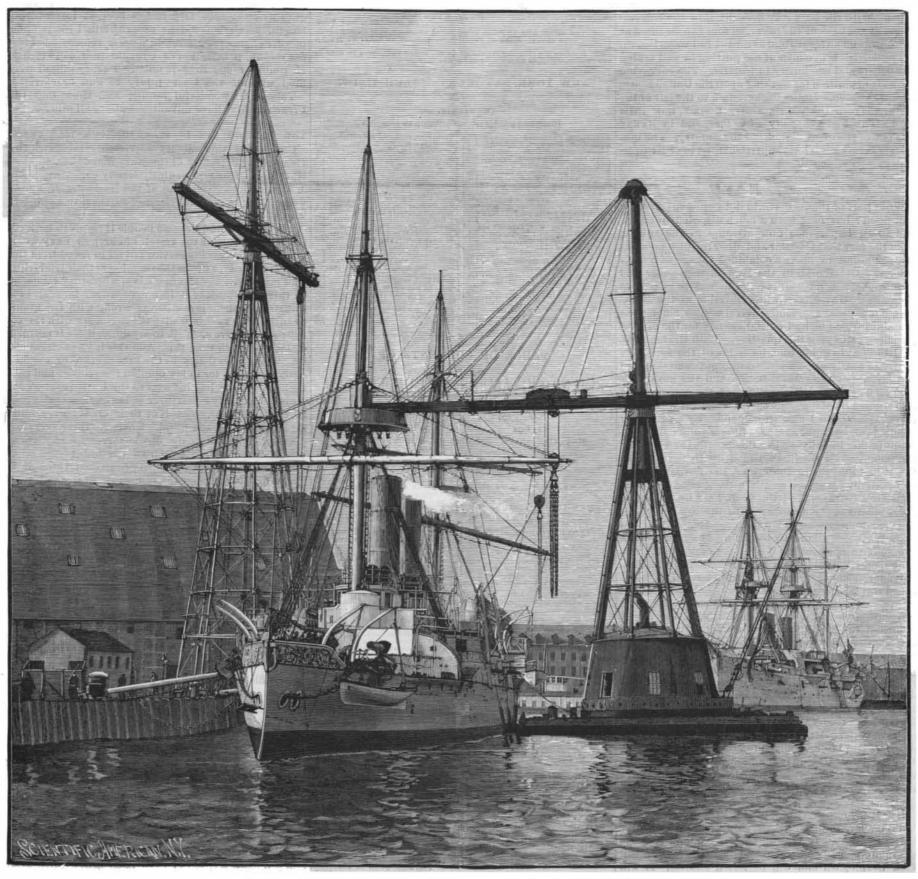

The structure is carried upon a pontoon, rectangular in shape, 60 feet wide by 63 feet long. The pontoon is divided into compartments, access to which is had through hatches or manholes, and is ballasted with 22 tons of cement ballast; the steel weighs in itself 70 tons. The superstructure is placed upon the long axis of the pontoon, and is a little advanced toward its front edge, in order to give the boom a greater reach. At its rear end there are five tanks for water ballast, and since its completion two auxiliary water tanks have been put in on each side. The object of these tanks is

to afford a counterballast during heavy lifting operations. In the pontoon is established a powerful pump with 6 and 8 inch connections, that can empty all the five main ballast tanks in half an hour. A couple of fire hose connections are provided, so that the pump can be used in an emergency as an auxiliary fire engine.

The tower is built of steel I beams and rods and contains 63 tons of metal. The base ring on which it stands rises 4 feet from the deck. Measured on the slope of the main struts, the length is 58 feet 8 inches to the first platform, termed the crow's nest, upon which the base of the king post rests. The struts continue above this until they reach the crown casting. The king post is 65 feet high; 14 feet 7 inches from its base it passes through the crown casting. Just above the crown casting the front and back booms are connected to it. The back boom is a box girder made up of plates and angle irons, and is 2 feet square, weighing 64 tons. The two members of the front boom are

16½ inch I beams, spaced far enough apart for the sheaves and tackle to work between. The object of the back boom is simply to afford a point of attachment with advantageous leverage for the back stays. These may be fastened at one of two points. As shown in the drawing, they are attached to what is known as the ball carriages, that work upon a circular railroad that runs around the base ring. When thus connected the boom can be swung around, the ball carriages traveling around the base also. For very heavy lifting the back stays are disconnected from the ball carriages and are secured upon turn buckles placed upon the after edge of the pontoon, thus increasing their power, but at the same time preventing the boom from being swung.

from its base it passes through the crown casting. Just above the crown casting the front and back booms are connected to it. The back boom is a box girder made up of plates and angle irons, and is 2 feet square, weighing to $6\frac{1}{10}$ tons. The two members of the front boom are

THE NEW STEEL FLOATING DERRICK AT THE BROOKLYN NAVY YARD.

ing. At the end of the boom stationary sheaves are secured, and tackle is provided for drawing the sliding carriage in and out, according to requirements. In order to rotate the beam, a single line of steel rope is carried around the base ring bearing against a number of rollers set vertically. The ends of the rope are secured to the ball carriages at the end of the back stay. These ropes enter the engine room, and are carried to a windlass drum, and being pulled one way or the other draw the ball carriages around the base ring and cause the boom to swing as desired.

All tackle is carried to one main hoisting engine placed upon the deck of the pontoon in the engine house. This engine has two cylinders 8 by 14 inches. and by a system of worm gearing and clutches actuates any of the different windlass drums required. To give some idea of the size of the parts, it may be mentioned that the hoisting gear alone weighs 131/2 tons; that the lower main hoisting block, with its eight sheaves, each 26 inches in diameter and working on a 2½ inch steel pin, and receiving 1% inch steel wire rope, weighs 2,000 pounds.

As regards bearings, ball bearings are used at three places. One, as just mentioned, at the foot of the back stay, another at the foot of the king post, and another upon the crown casting directly under the booms. The sheaves in all the blocks have plain brass bearings.

Two windlasses are established upon the deck of the pontoon outside the house, and are driven by a Manton steam-capstan engine. These are useful in moving the pontoon and in many operations on shore or on a ship's deck.

The load limit is as follows: With the back stay secured to the after edge of the pontoon, 75 tons can be lifted with the sliding carriage at two-thirds the length of the boom, and at full boom length 50 tons can be lifted. With the back stay brought into the ball carriages at the base of the tower, 30 tons can be lifted at two-thirds boom length and 30 tons at full boom length.

The derrick is in constant use putting in and taking any failure, delay, or irregularity in receipt of papers. out boilers and machinery in general. The engraving shows it in position for working upon the United States steamer Boston. In the background, to the left of the picture, is seen the old stationary derrick, now little used. This had a capacity of 60 tons, and in its day was one of the great derricks of the country. The new system favors a less lofty superstructure, in order to se cure greater strength.

Miscellaneous Notes.

What part of the New World did Columbus first set foot upon? has long been a much disputed question, and added importance now attaches to the subject from the fact that Castelar and other Spanish notables are proposing to make a combined voyage of vessels from the Old World to the New in September and October, 1892, as a feature of the honors to be paid to Columbus. Gov. Blake, while Governor of the Bahamas, a few years ago, made several cruises among the islands of which he had official charge, for the express purpose of studying this question. With the log book of Columbus to guide him, he followed the explorer's course as nearly as possible. A draughtsman sketched the outlines of the various shores, and the governor's wife made water color drawings of the scenery. He also studied the dangerous currents against which the early explorers had also to contend. By a process of elimination, one after another of the islands was rejected, as failing to fully satisfy the description given by Columbus, while Watling's Island wholly agreed with it. It had the lake in the center, the fertile soil, the reef encircling it except at the capacious harbor with its narrow entrance, and the bluff hard by. Such an independent study, together with the conclusions of the geographers who had not themselves seen it, entitles Watling's Island to be definitely considered as the spot seen when the joyful cry of "Land!" was raised, and indeed it has been officially named San Salvador, although many authors have heretofore called Cat Island San Salvador.

A curious incident in connection with the recent launch of the Royal Arthur at Portsmouth, England, is made the subject of a sketch by a London illustrated paper. No sooner had the water become quiet after the vessel left the ways, than numerous small boats appeared upon the scene, and their occupants, equipped with a variety of long-handled scoops, began to collect the grease floating upon the surface, and which had been used to insure the slipping of the vessel smoothly into the water. It is said that several hundredweight of grease had been employed for this purpose, and the thrifty boatmen would undoubtedly be able to dispose of their unique variety of flotsam for similar dockyard service in the future.

MR. RENARD, the distinguished French aeronaut, is building a new dirigible air ship of over 3,000 cubic vards capacity. It is said that the motor is made of aluminum and operates perfectly. The balloon will soon be finished and will be tested shortly. It will leave Meudon and maneuver between Versailles and Paris.

Scientific American.

ESTABLISHED 1845.

MUNN & CO., Editors and Proprietors. PUBLISHED WEEKLY AT

No. 361 BROADWAY, NEW YORK.

O. D. MUNN.

TERMS FOR THE SCIENTIFIC AMERICAN. One copy, six months, for the U.S., Canada or Mexico. One copy, one year, to any foreign country belonging to Postal Union. 4 00 Remit by postal or express money order, or by bank draft or check.

MUNN & CO., 361 Broadway, corner of Franklin Street, New York. The Scientific American Supplement

s a distinct paper from the SCIENTIFIC AMERICAN. THE SUPPLEMENT is a distinct paper from the SCIENTIFIC AMERICAN. THE SUPPLEMENT is issued weekly. Every number contains 16 octavo pages, uniform in size with SCIENTIFIC AMERICAN. Terms of subscription for SUPPLEMENT, 85.00 a year, for U. S., Canada or Mexico. 86.00 a year to foreign countries belonging to the Postal Union. Single copies, 10 cents. Sold yall newsdealers throughout the country. Bee prospectus last page. Comblued Kates.—The SCIENTIFIC AMERICAN and SUPPLEMENT will be sent for one year, to any address in U. S., Canada or Mexico, or receipt of seven dollars. To foreign Countries within Postal Union, nine dollars a new.

Building Edition.

THE ARCHITECTS AND BUILDERS EDITION OF THE SCIENTIFIC AMERICAN is a large and splendid illustrated periodical, issued monthly, containing floor plans, perspective views, and sheets of constructive details pertaining to modern architecture. Each number is illustrated with beautiful plates, showing desirable dwellings, public buildings and architectural work in great variety. To builders and all who contemplate building this work is invaluable. Has the largest circulation of any architectural publication in the world.

Single copies 25 cents. By mail, to any part of the United States, Canada or Mexico, \$2.50 a year. To foreign Postal Union councies, \$3.00 a year. Combined rate for BUILDING EDITION with SCIENTIFIC AMERICAN, \$5.00 a year, a vear; combined rate for BUILDING EDITION SCIENTIFIC AMERICAN and SUPPLEMENT, \$3.50 a year. To foreign countries, \$11.50 a year.

Spanish Edition of the Scientific American.

AMERICA CIENTIFICA E INDUSTRIAL (Spanish trade edition of NTIFIC AMERICAN) is published monthly, uniform in size and t SCIENTIFIC AMERICAN) is published monthly, uniform in size and typography with the SCIENTIFIC AMERICAN. Every number of La America is profusely illustrated. It is the finest scientific, industrial trade paper printed in the Spanish language, It circulates throughout Cuba, the West Indies, Mexico, Central and South America, Span; and Spanish possessions—wherever the Spanish language is spoken. \$3.00 a year, post paid to any part of the world. Single copies 25 cents. See prospectus,

TABLE OF CONTENTS OF

SCIENTIFIC AMERICAN SUPPLEMENT

No. 794.

For the Week Ending March 21, 1891.

Price 10 cents. For sale by all newsdealers

 BOTANY.—New Race of Dwarf Dahlias.—A new and valuable flowering plant, with portrait of the introducer.—1 illustration.... 1963 CHEMISTRY.—Carbon in •rganic Substances.—By J. MESSIN-GER.—An improved method of determining carbon by inorganic combustions.—1 illustration

12693

III. CIVIL ENGINEERING.—A New Integrator.—By Prof. KARL PEARSON, M. A.—An apparatus for use for the engineer in working up areas, indicator diagrams, etc.—4 illustrations...

Best Diameter of Car Wheels.—The size of car wheels from the standpoint of American engineering.—A plea for a moderate sized wheel standpoint of American engineering. A property wheel.

Improved Overhead Steam Traveling Crane—A crane constructed for use in steel works.—Great power and range—3 illustrated for tell. 12679 trations. 12079

Some Hints on Spiking Track.—A most practical article for telling exactly how to conduct the operation on the ground.—I illustration. 12681

ETf1NOLOGY.—Some Winnebago Arts.—An interesting article upon the arts of the Winnebago indians.—A recent paper before the New York Academy of Sciences.

VII. MUSIC.—Spacing the Frets on a Banjo Neck.—By Prof. C. W. MacCord.—A most practical treatment of this subject, with full explanations.—I illustration.

PHVSICS.—Armo-Picnometer.—An entirely novel form of hydrometer, of very extended use and application.—1 illustration.... 12657

TECHNOLOGY.—Fabric for Upholstery Purposes.—Full technical description of the methodof producing a new and characteristic description of the methodof producing a new and characteristic fabric.—I illustration.

Gaseous Illuminants.—By Prof. VIVIAN B. LEWES.—Continuation of this important article, treating of the water gas and special processes, with analyses.

12688
Glove Making.—Early history of glove making in America.—Its present aspects and processes.

12686
Reversible Ingrain or Pro-Brussels Carpet.—An imitation of Brussels carpet on the Ingrain principle.—Full description of the process of making.—3 illustrations.

The Manufacture and Use of Plaster of Paris.—An excellent treatment of a subject hithertolittle written about.—Full particulars of the manufacturing process

THE GREAT GUNS OF THE JAPANESE NAVY.

The attention of naval and military authorities has been strongly drawn of late to the remarkable differences in the effective power of the heavy guns of English make and those of the French.

The 110 ton guns of the English navy, constructed at immense cost, represent the latest and most formidable type of armament which Britain has produced. If the calculations of the makers could be realized in practice, the power of these guns would be astonishing. They are 43 ft. 8 in. long, 161/4 in. bore, intended to sustain a charge of 960 lb. of powder, carry a projectile of 1,800 lb. with a muzzle velocity of 2,128 ft. per second, equal to penetration of almost 34 inches of wrought iron. Several trials of these guns have been made with charges much below the maximum, and in every instance the guns have been so much injured as to render it dangerous to subject them to full tests. The latest trial was that of the 110 ton gun of the war ship Sans Pareil, at Shoeburyness, with a moderate charge of powder. The result was the bore of the gun was found to have drooped and also to have become laterally deflected. This is much to be regretted, for the gun is a magnificent specimen of mechanical construction.

In France the great company known as the Forges et Chantiers de la Mediterranee, at Havre, under contract with the Japanese government, have produced some large Canet guns for the war vessels of that nation, which must be conceded to stand at the present time in the front rank. Japan may be said to beat the world in the actual power of her heavy guns. They have been subjected to the severest tests, no expense having been spared in these trials to render them sure and effective. Each round fired cost \$2,000, and some \$40,000 in all were spent for the purpose. These guns weigh 66 tons, 121/2 inches bore, 41 feet 8 inches length, maximum weight of projectile 1,034 pounds, powder charge 562.2 pounds, muzzle velocity 2,262 feet per second, penetration of wrought iron 45.16 inches. Maximum range over 13 miles. Twenty rounds were fired without the least injury to gun or carriage.

These are wonderful results, and show that the French makers have advantages above all others.

---THE FALLING OFF IN SPEED OF OUR WAR SHIPS,

Concerning this subject we recently presented the views of the Secretary of the Navy and of Mr. Charles H. Cramp. Our representative lately called upon Mr. J. Taylor Ganse, president of the Harlan & Hollingsworth Company, with reference to the same subject, who said:

"It is a fact, and to some people it seems to be a remarkable one, that the vessels of our new navy when in ordinary every-day service fall off in speed from the high standard set up on the occasion of their trial trips. And many critics of the new navy, when they comment on this fact, speak of it in a deprecatory tone, and insinuate that there is something wrong with the architecture of the vessels or with the engines or with the efficiency of the crew. Well, to my mind, there is nothing easier to explain than this. And this is just as it should be. There is no defect in the architecture or engines of these vessels, for in my opinion the cruisers and battleships recently handed over to the United States government are fully equal in sea-going qualities and general efficiency to any vessels of their classes ever built for any nation in the world. There are three very simple and, it seems to me, obvious reasons why these vessels do not maintain their trial records:

First. The object of putting a vessel through a trial trip is to see what the utmost speed is which that vessel can possibly attain. It is not in actual service. The contractors see in the horizon one little word, speed, and with that before them they shape their course. They are on dress parade, and the every-day regulation incidents, such as heavy guns, ammunition for the guns and for the hungry crew, appliances, etc., are laid aside. It is now or never with the builders. But when it comes to ordinary running, the circumstances are changed. The vessels are laden with guns, with provisions, and with all the necessary outfit for a long voyage. All of this means weight; and with this enormous additional weight she puts to sea, with her decks nearer the surface of the water, and with a consequently augmented displacement. But this makes it more difficult to propel her through the water, and her speed must therefore suffer.

Secondly. An iron bottom when exposed to sea service for any length of time begins to foul, to accumulate vegetable growths, and the longer a vessel is in the water the greater will be this growth, and consequently the greater will be the deterioration in speed from that of the trial trip, when the bottom was clean and free from anything that would retard the speed of the vessel. This retardation in cases where a vessel has been in the water for a month is immense, and this one act alone would be enough to cause a great falling off in speed. In fact it is not too much to say that, all other things being equal, a vessel with a clean bottom can make a speed of twenty-five knots in the same time it would take a vessel with a foul bottom to make 12635 ten knots.
