Inventions. Aew

Improvement in Carriage Axles.

W. D. Titus and J. Atkiss, of Brooklyn, N. Y., have invented an improvement in carriage axles and their bearings. The nature of the invention consists, first, in making the journals of carriage axles of two cones arranged in a horizontal position, their apexes placed against each other, each of them being provided with a collar or shoulder, which fits snugly in either end of the hub and serves as a washer to prevent the escape of the oil. The outer of said cones being made movable, is fitted snugly over the square end of the journal after the wheel has been placed on the axle, and is held in place by means of a screw cap and spring catch, saiddevices serving to lock the hub and axle together. It consists, second, in providing the double conical journal box with an oil chamber formed round the two cones, and made to supply oil at the point where the apexes of the cones meet. The inventors have applied for a patent.

Rock Drill.

Anthony Frasier, of Sault Ste. Marie, Mich. has invented certain improvements in machines for drilling rocks, on which he has applied for a patent. The invention consists in placing the drill bar in a short sliding box, having one loose and three fixed sides-the loose side being so arranged and operated by a crank movement through a pitman, rocking pawl, and cam that its whole surface is caused to exert friction in a straight line upon the drill bar, which is thus] firmly held between this and the remaining sides of the box, and is elevated until the upper end of the pawl coming in contact with an inclined plate, releases the bar, and it descends by its own weight. The box holding the bar is slightly turned during its upward movement by an eye-pin loosely inserted in its side, and the drill is thus rotated.

Improved Miter Box.

Caleb Willis, of Mystic Bridge, Conn., has invented an improved cast-iron adjustable Miter Box, on which he has applied for a patent. The nature of the invention consists in making a cast-iron miter-box capable of turning in any desired direction, so that it may be set to saw any angle between one of 45°, and a rightangle and to guide the saw in a vertical or inclined direction. Each of the guide pieces or boxes is provided with a slotted vertical follower, which rests on the back of the saw and guides or facilitates its operation.

Improvement in Printing Presses.

W. H. Street, of New York City, has invent ed a new device for attaching the blankets to the cylinders of printing presses. The present mode of attaching them is by sewing, and this method is liable to some objections. This invention consists in the employment, for the purpose specified, of a series of pins arranged within the cylinder, a toothed bar, and an outer and inner screw, by the action of which one end of the blanket is held while the other is attached to the cylinder, the screws being for the purpose of drawing the blanket to the required degree of tension. A patent has been applied for.

Improved Car Coupling.

T. B. Stout, of Keyport, N. J., has made application for a patent upon an improved car coupling, the nature of which consists in securing the lower end of the bolt which passes

ped into tubes immediately below. These tubes teeth, O O, are arranged to open the furrows

The ratchet, R, working in the pawl, Q, atthe lower bar, and passing through the slot in tached to the shaft of the graduating roller,

When it is desired to plant but one row at a time, the side beams, B, and one of the hopper boxes are detached, and the other is placed upon the center beam, D; or if it be desired to

ends of the horizontal tube, K. This tube is ther information can be obtained by addressing formed in two parts, one at each end, which are the inventor as above. One of these Cultiva connected by an intermediate shaft. The ends tors is on Exhibition at the Crystal Palace.

S, in fig. 1 is the spring resting upon its support, B, CC, are bolts passing through the Fig. 2.

timbers of the truck, sustaining this support .---D D, are levers against which press the boxes of the car axles. These levers working over the fulcrums, E E, act upon the connecting rods, F F, which by means of the cross bar at their top, press upon the piston rod G, and consequently compress the air in the chamber, A, fig. 2 below the diaphragm, B B. C, is the piston rod, being the lower extremity of F, fig. 1. It will be seen that between the upper part of the diaphragm and the lower portion or therubber, there is arranged as before said, a series of concentric rings which protect the rubber from the action of the piston. The claim of the patent is upon this described construction of the diaphragm.

Locking Type Forms in Chases.

E. H. Sprague, of Zanesville, Ohio, has invented a new Chase Lock for locking up printer's torms. The form is locked by means of a combination of taper bars and wedges, with a compound lever or key, said bars being so arranged that the parallel side of one bears against the chase, and that of the other against the type, and their tapering sides against the wedge, by the action of which they are forced apart. Application has been made for a patent.

Heliographic Engraving.

We have received from M. Niepce de St. Victor, the heliographic steel engravings transmitted to us by the kindness of M. Gardissal. These engravings are, as will be remembered, etched by the action of light, and are not at any time touched by the hand of the engraver. The plates are very perfect, it scarcely seems possible that such an effect can be produced, yet M. de St. Victor assures us that they have not been re-touched. This art may yet be to that of the engraver what photography is to the painter.

Emery Sand Paper.

This kind of paper being made with glue, it is liable to be injured by moisture and water : a water-proof substance, as a substitute for glue, is therefore desirable. It has been proposed to use a solution of gum-copal in hot linseed oil, some turpentine, litharge, and dissolved india rubber. A cement made of these substances, we think, would answer a good purpose.

Brilliant Varnish for Leather.

Take 4 oz. shellac, half an oz. of lamp-black, and place them in a stone-ware vessel, into which pour about 12 lbs. of alcohol, and cover it with a moist bladder. Let them be frequently shaken for about 24 hours. After this puncture the bladder, and add half an ounce of turpentine and leave the whole for about 24 hours onger. Repeated applications of this will crack the leather, but for some purposes it is very useful.

through the link between springs, in such a manner that the springs, when a car is thrown from the track, will be acted upon by a lateral movement of the bolt, caused by the pressure of the link upon it, and release the link from the bolt. This may also be done by a lever operated by the brakeman while the cars are in motion.

The Japanese as Inventors.

Bayard Taylor says "the peculiar talent of the Chinese is imitation. The Japanese do not content themselves with this, but are probably, next to the Yankees, the most inquiring race in the world, and would be inventors were it not for the restrictions of Government.

The engravings herewith presented represent | in the cylinder which occasioned so much friction an improvement in pneumatic springs, especial- as to cause rapid wear, and consequently, a raply adapted to railway carriages, a patent for which id destruction. In this improvement, these obwas granted to Elijah Ware, of Roxbury, Mass. jections are obviated, as the piston instead of July 6, 1852. Fig. 1 is a side view of a car wearing on the sides of the cylinder has fitted truck containing this improvement, and fig. 2 into it a moveable diaphragm, which presses is a section of the spring. against a disk of rubber or some similar sub-

This kind of car springs as previously con- stance, which is forced against the air in a structed, consisted of a cylinder with a piston chamber beyond, this diaphragm having confitting very accurately within it, and working centric rings placed on it to prevent the rubber against the compressed air. The objection to from being worn. In pneumatic springs where this mode of construction has been that in or- a similar disk has been used, the piston has actder to render the spring air tight, it has been ed directly upon the rubber, which was consenecessary to make the piston play very tightly quently soon destroyed by its action.

In the construction of the new Pacific Mills in Lawrence, Mass., wooden pillars or supporters are used in the buildings. A hole is bored through the center of each of these supporters, about an inch in diameter, connecting at each end with the outer air, by means of a small perforation in the side of the post .-This admits a free circulation of air on the inside as well as on the outside of the wood; in this manner the wood is rendered much more durable, without any sacrifice of strength.
