Inbentions.

Feeding Printing Presses

Henry E. Chapman of Albany, N. Y. has invented an apparatus for feeding paper to printing presses, on which he has applied for a patent. The invention consists in the use of a vibrating frame composed of a series of air tubes in combination with a series of fingers attached to the vibrating frame and moving with it, and also having a movement independent of the frame. The air tubes above mentioned communicate with a bellows or air pump, which operates as the trame vibrates and gives an alternate attractive and repelling surface to the ends of the several tubes of the frame, which in connection with the fingers convey the paper in single sheets to the press. The novelty consists in the combination of the fingers with the vibrating frame and air tubes.

Preparing Gold.

A. J. Watts of Utica, N. Y. has invented an improved process of preparing gold for Dental purposes, and others of a similar character. The nature of this invention consists in submitting spongy crystaline gold to certain degrees of heat, varying according to the spongy character of the specimens to be treated, whereby it is rendered adhesive, cohesive, and malleable, which enables it to accommodate itself to all the irregularities and cavities of the teeth. Application has been made for a patent.

Railroad Switches.

George Hancock of Providence, R. I. has invented an improved railroad switch, and has taken measures to secure a patent. This invention consists in the employment of a number of elastic and permanent rails attached to movable frogs so arranged that the cars while going in one direction may be switched on branch tracks at either side of the road, while cars moving in an opposite direction may pass over the switch on the main track, irrespective of the position of the switch.

Improved Wrench.

P. Smith of Bridgeport, Conn. has invented an improved wrench, on which an application has been made for a patent. The nature of the invention consist in having the lower jaw of the wrench stationary and secured to the handle by a hollow shaft, while the other jaw is made movable by a combination of a rack and pinnion.

Ditching Machine.

John Lyon of Harrisburg, Iowa, has invented a machine for excavating earth and throwing it in embankments, on which application has been made for a patent. The machine is constructed with a plow, which enters the ground and elevating the earth throws it upon the endless conveyor moving at right angles to the line of draught. The claim is upon the general arrangement of parts.

Improved Slitting Gauge.

James Ballard, of Ashtabula, Obio, has invented an improvement in gauges for slitting laths and like purposes, on which he has applied for a patent. The invention consists in making the gauge head in two sections with back stops and set screws, and uniting them together at their center, by a pin upon which they may turn freely, and the lower section adjust itself to a position in line with the edge of the board, thus preventing it from running off in cross grained wood.

Improved Lantern.

P. A. Morley, of Brooklyn, N. Y., has invented an improvement in Lanterns, on which he has taken measures to secure a patent. The improvement consists in making a lamp and lantern in one piece of glass, thus simplifying its construction and reducing its cost, as no fastenings' are necessary for securing the oil reservoir to the lantern.

On account of the tremendous mortality by pulmonary consumption, it has been suggested that a distinct chair in some or all of the colleges, for the study of thoracic viscera, and the lungs in particu'ar, in health and disease, would

LYMAN'S APPARATUS FOR WARMING AND VENTILATING ROOMS.

the heat of the furnace through separate and more extensive radiatory surfaces.

These radiators constitute a chamber completely inclosing the furnace, and being air tight they do not permit any of the air that has from their joints, to pass up into the rooms.

From their position and extent the radiators the same manner as water in the common hot are uniformly heated by hot air, so that the ing with the furnace of the hot water apparawater apparatus, as the medium for diffusing current of air passing along their outer surfaces tus; B is a large corrugated smoke chamber for warming and ventilating is uninjured, havsurfaces, or mingled with noxious gases.

as it is so over-heatedby the high temperature to health.

The products of combustion escaping through the joints of the furnace into the rooms are inhaled by the occupants. This is not entirely owing to defects in the construction of, or accidents to furnaces, but in part to their peculiar situation. Placed in chambers of rarified air, from which proceed upward large flues having often a draught more powerful than that of the smoke pipe, and the supply of cold air being checked by adverse currents or eddy winds about the entrance of the cold air channel or by the valve being partly closed in this channel, while the draught under the grate is fully open, the pressure of the atmosphere often becomes greater in the furnace than in the rarified air chamber around it, consequently the products of combustion are forced through the joints of the furnace to supply the partial vacuum.

Again, every one knows that smoke and gas frequently escape from the joints of the common stove when the door is open, and also when the damper in the smoke pipe is shut. This is true to a much greater extent in the case

of the furnace surrounded by a partial vacuum. The frequent fires which have occurred from furnaces, have rendered the very word almost a terror to many housekeepers. They are far from being all alike dangerous, but very many of them are neither more safe nor economical than that styled by Dr. Ure, "an incendiary coal devourer." The powerful draught up the hot air pipes, and the partial vacuum in the chamber surrounding the furnace causes not only the gases to escape as above shown, but sometimes sparks of fire escape by the joints of the furnace, and passing up with the current through the register set fire to articles in the room, or glancing through the joints of the hot air pipe, more frequently set fire to the woodwork which between the partitions and under the floor is covered with a dry inflammable powder. This more surely results when from undiscovered flaws and expansion by heat, pieces of the furnace are broken out which is not unfrequently the case.

This apparatus has been in operation at the Novelty Works during the whole of the past wininternal furnace mingle with the circulating me- the radiators, R, being warmed, rises up the ter and has within a few past weeks been ordered for several first class houses, among others the new Opera House, on 14th street, where a support combustion is sent off the smoke pipe case, and under the shield through the radia-room 200 feet long, 120 wide, and 85 high is to be heated by it.
